I. Introduction

The following report describes existing natural resources and conditions which may be impacted by the various Alternatives within the study area of the Interstate 64 (I-64) Peninsula Study. The purpose of this report is to summarize baseline conditions along the property, provide a comparison of the impacts to these resources for the different Alternatives, and summarize potential permits or environmental clearances needed prior to the construction of the project. This information can also serve as a basis for the Indirect and Cumulative Impacts Analysis.

A. Project Description

The Virginia Department of Transportation (VDOT), in cooperation with the Federal Highway Administration (FHWA), is evaluating options to improve the 75 mile long Interstate 64 (I-64) corridor from the Interstate 95 (I-95) (Exit 190) interchange in the City of Richmond to the Interstate 664 (I-664) (Exit 264) interchange in the City of Hampton. This study is known as the Interstate 64 Peninsula Study (hereinafter referred to as the I-64 Study in this document). As shown in **Figure 1**, the study area is located within seven localities, including the City of Richmond, Henrico County, New Kent County, James City County, York County, the City of Newport News, and the City of Hampton.

The number of lanes on existing I-64 varies through the study area. In the vicinity of the City of Richmond, from Exit 190 to Exit 197, there are generally three travel lanes in each direction. Between Exit 197 and mile marker 254, there are generally two travel lanes in each direction. Beginning at mile marker 254 and continuing east to the City of Hampton area, I-64 widens to four lanes in each direction with three general purpose lanes and one 2+ person High Occupancy Vehicle (HOV 2+) lane during the AM and PM peak periods. There are some additional lanes between closely spaced interchanges at the eastern end of the corridor to provide for easier merging of traffic on and off of the I-64 mainline.

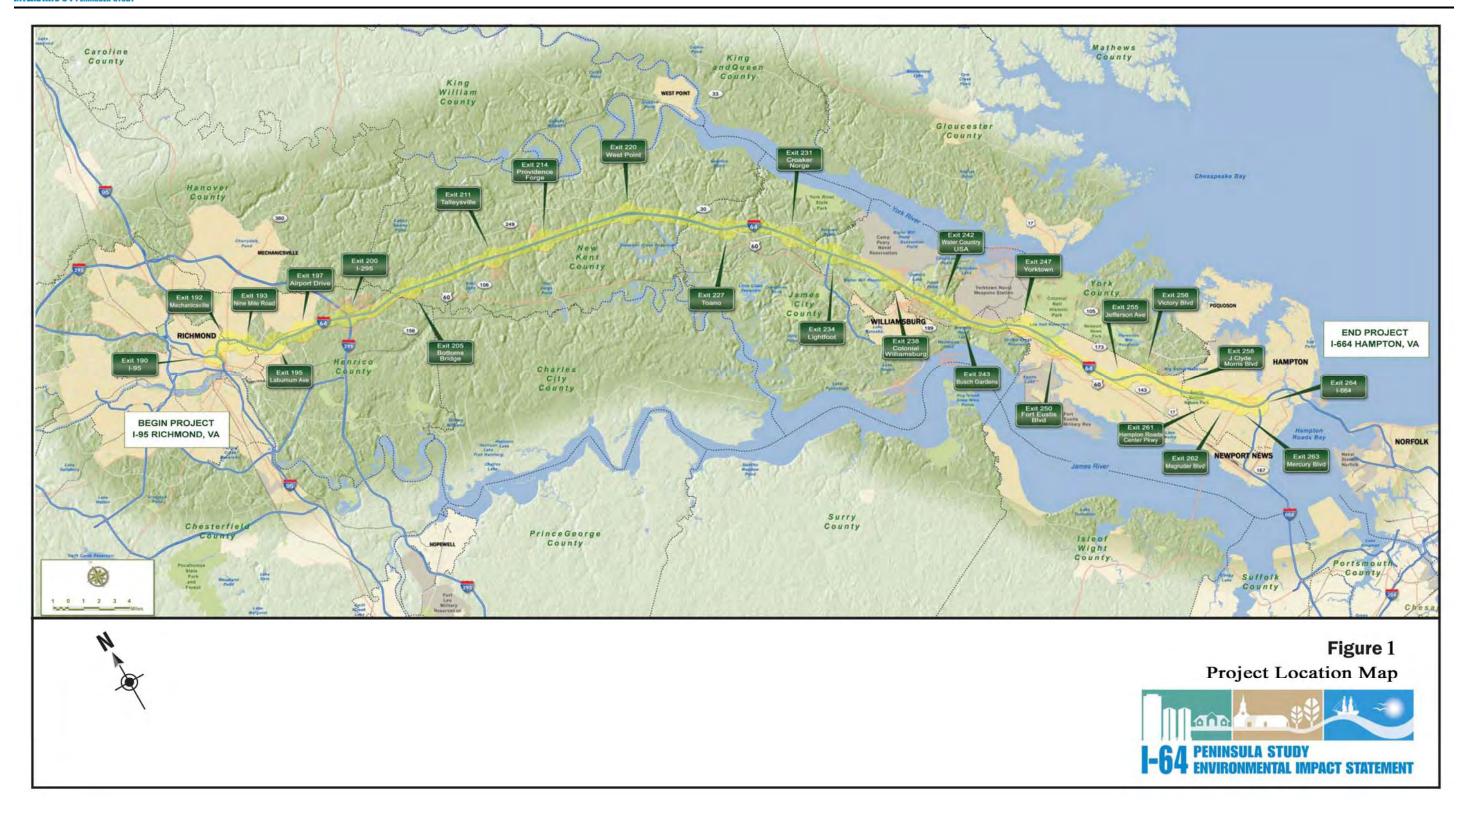

B. Alternatives

There are a number of possible solutions to address the need for improvements along the I-64 corridor, as described in detail in the *Alternatives Development Technical Memorandum*. The goals are to develop solutions that meet the project purpose and needs while avoiding and/or minimizing impacts to the human and natural environments. The following are the Alternatives being carried forward in this study:

1. No-Build Alternative

The No-Build Alternative serves as a baseline for the comparison of future conditions and impacts. The No-Build Alternative assumes that the projects currently programmed and funded in the VDOT's Fiscal Year 2013 - 2018 Six-Year Improvement Program (SYIP) will be implemented. In addition to the programmed VDOT projects, the Tidewater Super-Regional Model developed by VDOT and used for this study includes other projects within the corridor that are part of the Richmond Area Metropolitan Planning Organization (MPO) or Hampton Roads Transportation Planning Organization's (TPO) Constrained Long Range Plans, as well as the Rural Long Range Transportation Plans (which are not fiscally constrained) for the Richmond and Hampton Roads Planning District Commissions. Those projects form a part of the Base Conditions and the effects of these projects on I-64 traffic are accounted for in all 2040 No-Build analyses.

2. Alternatives 1A/1B General Purpose Lanes

These Alternatives involve adding additional general purpose travel lanes to the I-64 mainline to achieve a Level of Service (LOS) C or better in the design year 2040. Although there are numerous possible combinations for adding these lanes, the analysis focused on adding all needed lanes within the existing right of way, to the greatest extent practicable, to either the outside of the existing lanes, which is Alternative 1A, or to the inside of the existing lanes within the median, which is Alternative 1B. For Alternative 1B, the lanes are also proposed in the median to the greatest extent practicable. However, not all sections of the corridor have sufficient median area to accommodate the needed additional lanes so in these areas the additional lanes are proposed to the outside. For the 25 existing interchanges within the study area corridor, geometric deficiencies were examined along with design year 2040 traffic volumes and resulting LOS at each interchange location. Conceptual designs were investigated that would accommodate the future traffic and assumptions were made and applied to each interchange to establish a study footprint that would allow for enough flexibility during the final design stage to accommodate other concepts not yet examined. Further engineering and traffic analyses would be performed at each interchange as the project progresses. During the Interchange Modification Report (IMR) process, which is required by FHWA before any changes can be made to Interstate interchanges, each of these interchange configurations would serve as a starting point to be further studied and refined with a more in-depth examination of the needs at each location, in order to produce a constructible design.

3. Alternatives 2A/2B Full Toll Lanes

These alternatives evaluate the impacts of tolling the entire facility. However, as of the time of this study, there is no federal or state agreement in place that would allow for tolling I-64 from I-95 in the City of Richmond to I-664 in the City of Hampton. Therefore, these alternatives that involve tolling may or may not ultimately be possible. Notwithstanding, because tolling could be an option in the future, alternatives that involve tolling were considered in the range of possible alternatives evaluated. For the purposes of this study, it was assumed that if the facility is tolled, the tolling would be for all vehicles, in both directions, and for the entire length of the corridor from I-95 in the City of Richmond to I-664 in the City of Hampton. It was also assumed that there would be toll collection stations, using overhead gantries and all-electronic tolling, for every interchange-to-interchange sections of I-64. If Alternative 2A or 2B is selected, subsequent studies would refine the specifics of the tolling, such as whether or not it would encompass the entire length of the I-64 corridor along with the number and placement of the toll collection stations. In order to determine the number of lanes needed for Alternatives 2A/2B, the traffic studies included a toll diversion analysis. As a result of this analysis, the tolling of I-64 is expected to have either a neutral effect or result in a decrease in traffic volumes on the I-64 mainline due to people choosing to avoid a tolled I-64 and using other parallel routes instead. The tolls are not expected to result in increased volumes at any location on the I-64 mainline. This analysis indicated possible reductions to traffic on the I-64 corridor, however these reductions are not projected to change the number of lanes needed to achieve a LOS C or better in the design year 2040 from those indicated for the General Purpose Lanes Alternatives. Therefore, the proposed disturbance limits for Alternatives 2A/2B would be the same as Alternatives 1A/1B, respectively. Although there are numerous possible combinations for adding these lanes, the analysis focused on adding all needed lanes within the existing right of way, to the greatest extent practicable, to either the outside of the existing lanes, which is Alternative 2A, or to the inside of the existing lanes within the median, which is Alternative 2B. For Alternative 2B, the lanes are also proposed in the median to the greatest extent practicable. However, not all sections of the corridor have sufficient median area to accommodate the needed additional lanes so in these areas the additional lanes are proposed to the outside. In addition to the mainline improvements, due to only modest changes in traffic volumes, as determined in the toll diversion analysis, Alternatives 2A/2B also includes the same improvements to the 25 interchanges as described with Alternatives 1A/1B.

4. Alternative 3 Managed Lanes

This Alternative involves the addition of separated, managed lanes located in the median. These managed lanes were examined for the entire length of the I-64 study area from I-95 in the City of Richmond to I-664 in the City of Hampton. As previously described, not all sections of the I-64 corridor have sufficient median area to accommodate the addition of any lanes. In these areas, the facility is proposed to be widened to the outside of the existing general purpose lanes in order to accommodate the managed lanes between the eastbound and westbound general purpose travel lanes. Managed lanes can refer to many different strategies, including:

- High Occupancy Vehicle (HOV) lanes.
- High Occupancy Toll (HOT) lanes.
- Express Toll Lanes (ETL).
- Express Bus Lanes (EBL).

For any of the managed lanes that involve toll collection (HOT or ETL lanes), traditional toll plazas were not included. All toll collection would be conducted by overhead gantries with all-electronic tolling used to collect all tolls at highway speeds. The Environmental Impact Statement (EIS) study does not identify what type of managed lanes would be constructed. Based on the results of the capacity analysis, the lane configurations developed for Alternative 3 along the I-64 corridor are described in the *Alternatives Development Technical Memorandum*. If Alternative 3 is selected, subsequent studies would refine the specifics of the managed lanes throughout the I-64 corridor.

II. Existing Conditions and Potential Impacts

The following sections summarize the existing natural environmental conditions that exist in the vicinity of the study corridor. A number of natural resources and specific conditions were identified within the study area of the I-64 Study, including:

- Topography.
- Geology and Soils.
- Surface waters
- Water quality
- Water supplies.
- Floodplains.
- Threatened and endangered species.
- Terrestrial and aquatic habitat and wildlife.
- Invasive species.

As part of the environmental review process for this study, various federal and state agencies were contacted and databases and websites were reviewed to determine the presence and status of the existing natural environmental conditions located within the study corridor. Several other environmental resource related features (e.g., parks and recreation areas, easements, prime farmlands, agricultural/forestal districts, etc.) are discussed in other reports developed for the EIS.

A. Topography

Methodology and Existing Conditions

The study area is located within the Coastal Plain Physiographic Province of Virginia. The Coastal Plain in Virginia extends inland from the coast about 110 miles to the Fall Line of Virginia and passes roughly through Fairfax County and the Cities of Fredericksburg, Richmond, Petersburg, and Emporia. The study corridor crosses two Coastal Plain sub-provinces: the Upland Sub-province and the Lowland Sub-province. The small sections of the corridor which cross the Coastal Upland Sub-province are

characterized as a broad upland with low slopes and gentle drainage divides. Steep slopes develop where the area is dissected by stream erosion. Elevations within this subprovince range from 60 - 250 feet above mean sea level (MSL). The majority of the study area corridor is generally characterized as coastal lowland drained by an elaborate network of streams and rivers, which flow east to the Atlantic Ocean. The Coastal Lowland Sub-province is flat, with low relief areas along major rivers and near coastal areas of the Chesapeake Bay. Elevations in the Coastal Lowlands are generally between 0-60 feet above mean MSL.

The length of the study corridor is north of the James River and south of the York River but crosses many major tributaries to these systems including the Chickahominy River at Bottoms Bridge and the headwaters of the Warwick River in Newport News. A dendritic network of creeks and small streams rise near the center of the landform and meander south and north to the James and York Rivers, respectively, producing a dissected landscape of ridges, steep slopes, and floodplains. The study area spans the following United States Geologic Survey (USGS) 7.5-minute quadrangle maps (from west to east): Richmond, Seven Pines, Quinton, Tunstall, Providence Forge, Walkers, Toano, Norge, Williamsburg, Hog Island, Yorktown, Mulberry Island, Newport News North, and Hampton. A topographic map showing the entire study area is included as **Figure 2**. This map was created using the Environmental Systems Research Institute (ESRI) World Topographic Map layer which was compiled to uniform cartography using a variety of best available sources from several data providers, including the USGS, United States Environmental Protection Agency (USEPA), United States National Park Service (NPS), Food and Agriculture Organization of the United Nations, Department of Natural Resources Canada, Agriculture and Agri-Food Canada, Dutch Kadaster, DeLorme, NAVTEQ, TomTom (select countries in Eastern Europe and select European island nations), and ESRI.

Within the study area, elevations range from 0 to 180 feet above MSL. According to the topographic maps of the area, the mean elevation through the proposed project area is approximately 82.14 feet above MSL.

Potential Impacts and Mitigation Measures

There is very little topographic relief along the corridor. In addition, the study involves potential widening along the existing, already disturbed I-64 corridor. In terms of topography, the highway corridor is already suitable for the proposed widening activities, and therefore, no adverse changes to topography would occur. No measures to mitigate potential topographic changes are warranted.

B. Geology

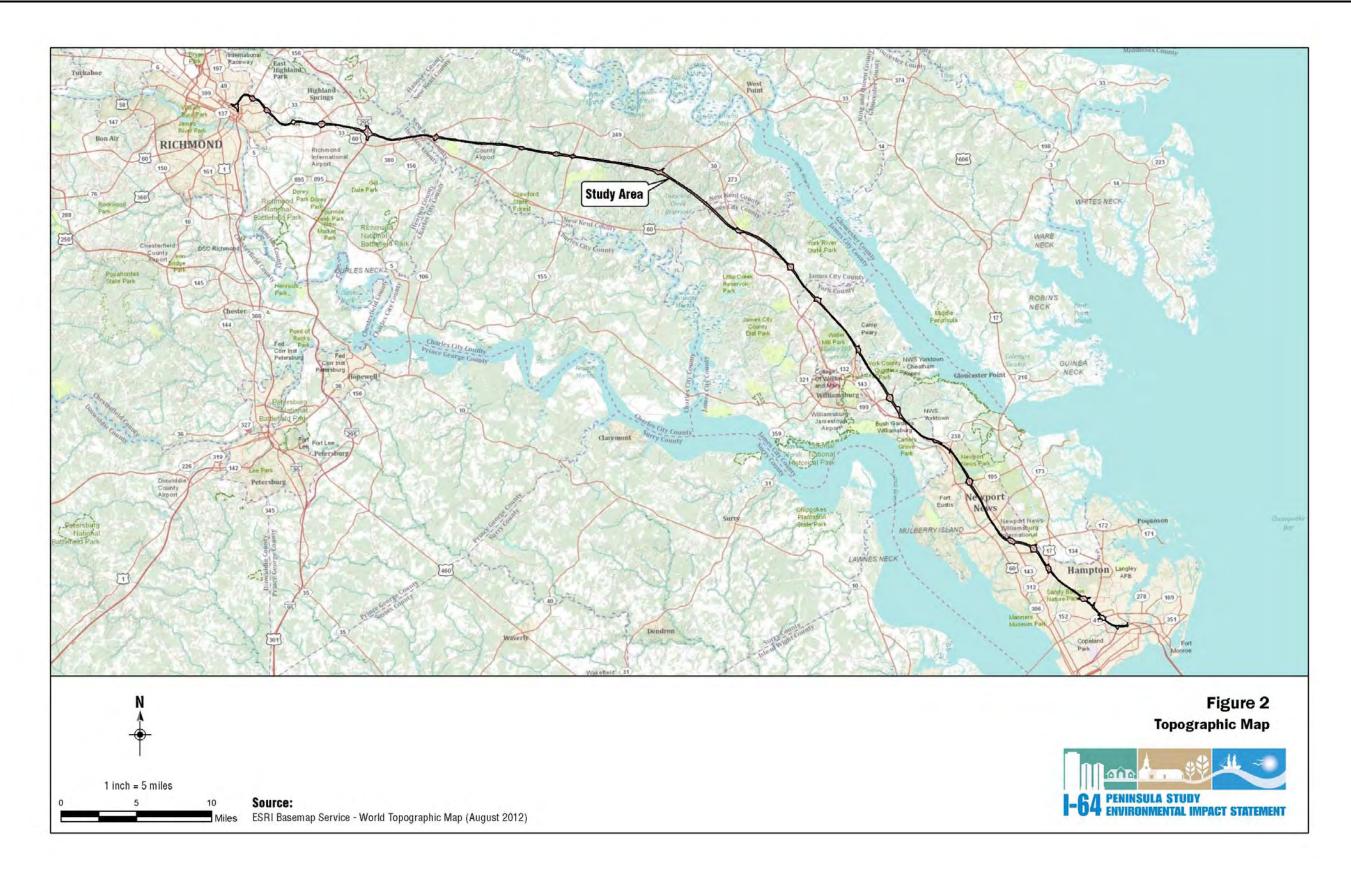

Methodology and Existing Conditions

The study area is located within the Coastal Plain Physiographic Province of Virginia. According to the Geologic Map of Virginia, the Coastal Plain is composed mostly of unconsolidated deposits, primarily alternating layers of sand, gravel, shell rock, silt, and clay. Geologically speaking, this physiographic province is still considered a young landscape sculpted during the last few million years by the repeated rising and falling of sea level during several cycles of Pleistocene glaciations.

The Coastal Plain, in general, is underlain by a thick wedge of sediments that increases in thickness from a featheredge near the fall zone to more than 4,000 meters under the continental shelf. These sediments rest on an eroded surface of Precambrian to early Mesozoic rock. Two-thirds of this wedge is comprised of late Jurassic and Cretaceous clay, sand, and gravel. These layers were stripped from the Appalachian mountains, carried eastward by rivers and deposited in deltas in the newly formed Atlantic Ocean basin.

A sequence of thin, fossiliferous marine sands of Tertiary age overlies the older strata. They were deposited in warm, shallow seas during repeated marine transgressions across the Coastal Plain. This pattern of deposition was interrupted about 35 million years ago by a large meteorite that plummeted into

a shallow sea, which created the Chesapeake Bay. It was subsequently buried under about 1.2 kilometers of younger sediment.

The latest soils of Tertiary and Quaternary sand, silt, and clay, which cover much of the Coastal Plain, were deposited during interglacial highstands of the sea under conditions similar to those that exist in the modern Chesapeake Bay and its tributaries.

The western end of the study corridor begins near the Fall Line of Virginia, a low escarpment where the sedimentary rocks of the Coastal Plain meet the metamorphic rocks of the Piedmont, and extends across the inner and outer Coastal Plain to the Chesapeake Bay. The Coastal Plain is a terraced landscape that steps down to the coast and to the major rivers.

The study area corridor includes both the Cenozoic Era Tertiary and Holocene formations. The corridor extending from the City of Richmond to south of the City of Williamsburg is underlain by Tertiary-age formations which consists of sand, mud, limey sand and muck. The Holocene-age formations, which consists of sand, marsh, and peat deposited in beaches, marshes, swamps, and estuaries underlies the eastern section of the corridor.

According to information provided by the Virginia Department of Conservation and Recreation (VDCR) through the project scoping process, there are no karst features located within the study area corridor.

Potential Impacts and Mitigation Measures

There are no geological conditions or unique geologic resources along the study area corridor that would be adversely affected by the proposed activities. Seismic risks are low and would not affect the construction or interstate operation. No mitigation action related to geological or seismic conditions is warranted. All limitations that may be associated with any geological constraints can be mitigated for through standard engineering practices.

C. Soils

Methodology and Existing Conditions

The study area is located within the Coastal Plain Physiographic Province of Virginia. Parent material in the Coastal Plain consists mainly of marine and alluvial deposits. It is very rich in quartz with most soils containing 50% with the highest concentration of up to 80-90%. Feldspars are also common in Coastal Plain parent material, but tend to be in lower quantity (up to 25%). Micas, iron oxides, heavy minerals and clay minerals are common in small amounts. Organic parent materials are common in the numerous swamps and marshes across the region.

The soils within the study area corridor were identified using the United States Department of Agriculture Soil (USDA) Natural Resources Conservation Service (NRCS) County Soil Surveys and digital mapping. Classified soils are grouped into general soil map units and have broad areas with distinctive patterns of soils, relief, and drainage. Each unit is named for the major soils it contains; however, a unit may also consist of several minor soil classifications. The soils in any one general soil map unit may differ across a region in slope, depth, drainage and other characteristics. The classified unit provides many details regarding the characteristics of the soil including soil structure or components, the ability to retain water, and how easily the soil erodes. For many counties/localities, there is a soil type identified as "NOT COM", which stands for "Not Complete", indicating a gap in the NRCS data.

According to NRCS, a hydric soil is a soil that formed under conditions of saturation, flooding, or ponding long enough during the growing season to develop anaerobic conditions in the upper part. The NRCS maintains the official list of hydric soils. The presence of hydric soils is required for the legal definition of a wetland.

Also according to NRCS, the likelihood of a soil type to erode can be expressed as a "K" value. The K factor is a soil erodibility factor which represents both susceptibility of soil to erosion and the rate of runoff, as measured under the standard unit plot condition. The higher the K value, the more easily the soil would erode. Soils high in clay have low K values (about 0.05 to 0.15) because they are resistant to detachment. Coarse textured soils, such as sandy soils, also have low K values (about 0.05 to 0.2) because of low runoff, even though these soils are easily detached. Medium textured soils, such as the silt loam soils, have a moderate K values (about 0.25 to 0.4) because they are moderately susceptible to detachment and they produce moderate runoff. Soils having a high silt content (K values greater than 0.4) are most erodible of all soils. They are easily detached, tend to crust, and produce high rates of runoff.

While the K value indicates the likelihood of a soil type to erode, there are a number of factors that also contribute to the soils erodibility. Organic matter reduces erodibility as it reduces the susceptibility of the soil to detachment and increases infiltration, reducing runoff and therefore, erosion. In addition, soil structure affects both susceptibility to detachment and infiltration. Permeability of the soil profile affects K because it affects runoff. Since the K factor represents soils in their natural state, the value may need to be increased if the subsoil is exposed or where the organic matter has been depleted, the soil's structure destroyed or soil compaction has reduced permeability.

There are a total of 115 soils map units within the study area, as identified from the NRCS Soil Survey Maps. The tables in **Appendix A** identify soil mapping units, along with general characteristics of those soil units, within the City of Richmond (14 soil map units), Henrico County (44 soil map units), New Kent County (36 soil map units), James City County (24 soil map units), York County (25 soil map units), City of Newport News (22 soil map units), and the City of Hampton (11 soil map units). It should be noted that the actual soil types throughout the study area, particularly in high population areas, may differ from the soil survey, primarily due to urban development that has occurred since the soil survey data was collected. Summary tables of the soil types and maps depicting the different soil types along the study area corridor are included in **Appendices A and B**, respectively.

There are a variety of soil units, with associated characteristics, identified across the corridor. Loamy soils, with a predominance of sand and silt, are common across the study area. Loam is a soil composed of sand, silt, and clay in approximate concentrations of 40-40-20%, respectively. Loam soils generally contain more nutrients and humus than sandy soils, have better drainage and infiltration of water and air than silty soils, and are easier to move through than clay soils.

Soils were identified ranging from somewhat extensively well drained to very poorly drained throughout the corridor. While varying ranges of soil drainage were identified throughout the corridor, the eastern part of the study area commonly exhibited poorly drained soils. In addition, hydric soils are located throughout the corridor and generally correspond to areas where wetland systems were identified (as described in Section D, below). In general, the depth to the water table decreases from west to east; however, the greatest water depths were associated with soil units located in the middle of the study area. There were varying levels of soil erodibility across the corridor with K values ranging from 0.1 (Catpoint fine sand in New Kent County; Nevarc-Uchee complex in New Kent County, James City County and the City of Newport News; Uchee loamy fine sand in New Kent County, James City County and the City of Newport News; and Seabrook-Urban land complex in Hampton City) to 0.49 (Duplin very fine sandy loam and Kempsville very fine sandy loam, clayey substratum in Henrico County).

The most prevalent soils, based on acreage within the study area corridor, are the Nevarc-Remlik complex found in New Kent and James City Counties. This soil unit is found on approximately 13% of the study area corridor and had the highest number of occurrences (202) along the corridor. The Chickahominy-Urban Land complex, found in York County and the Cities of Newport News and Hampton, and the

Kempsville-Emporia complex and Craven-Uchee complex, found in New Kent, James City, and York Counties, comprise approximately 18% (6% each) of the study area corridor.

Potential Impacts and Mitigation Measures

The proposed widening associated with the Build Alternatives would be built on the appropriate fill or cut materials. Soils used for this purpose would be subjected to specifications designed for the road building purposes. Any required mitigation of soils with substantial limitations would be resolved as part of the contract special provisions.

No substantial mitigation of soils with severe limitations is anticipated. Careful design and construction practices, as well as adherence to applicable erosion and sediment control regulations, stormwater management regulations, and on-site waste disposal regulations are sufficient to avoid impacts on soils. No mitigation measures are required.

D. Surface Waters

1. River Basin Information

The study area corridor falls within three of the twelve major river basins in Virginia, specifically the James River (Lower James River sub-basin), the York River, and the Chesapeake Bay/Atlantic Ocean and Small Coastal Basins. All drainage along the study area corridor ultimately flows from west to east, eventually entering the Chesapeake Bay. The following provides additional information on the major river basins and areas located along the study area corridor.

The USGS has assigned a hydrologic unit code (HUC) to all major watersheds in the United States. The western section of the corridor is located in the Lower James River watershed (HUC 02080206), with the drainage throughout this area of the corridor generally flowing to the south. The study area then drains to the northeast to the York River watershed (HUC 02080107). In York County, drainage again flows to the Lower James River watershed (HUC 02080206). The eastern section of the study area corridor drains to the Chesapeake Bay-Lynnhaven-Poquoson watershed (HUC 02080108). Table 1 describes the locations of the three major river basins along the corridor. In addition, the HUC eight digit watersheds are included on the mapping in Appendix C.

The James River Basin occupies the central portion of Virginia and covers 10,265 square miles or approximately 24% of the Commonwealth's total land area. As Virginia's largest river basin, it is composed of the Upper, Middle, and Lower James River sub-basins, as well as, the Appomattox River sub-basin. The James River Basin begins in the Alleghany Mountains and flows in a southeasterly direction to Hampton Roads where it enters the Chesapeake Bay. The river is formed by the confluence of the Jackson and Cowpasture Rivers and flows 242 miles to the Fall Line at the City of Richmond and another 106 miles to the Bay. Other major tributaries to the James River (from west to east) include the Maury River, Tye River, Rockfish River, Slate River, Rivanna River, Willis River, Appomattox River, Chickahominy River, Pagan River, Nansemond River, and the Elizabeth River.

The topography of the James River Basin varies throughout the four physiographic provinces that it spans. For the area west of the City of Richmond, the Piedmont Province extends to the Fall Line in the City of Richmond with scattered hills and small mountains, gradually turning into gently rolling slopes and lower elevation in the eastern portion of the province. The Fall Zone, which separates the Coastal Plain Province from the Piedmont Province, is a three mile stretch of river running through the City of Richmond where the river descends 84 feet as it flows from the resistant rocks of the Piedmont to the softer sediments of the Coastal Plain. Over 65% of the entire James River Basin is forested, with 19% in cropland and pasture. Approximately 12% is considered urban. The population of the entire James River Basin is concentrated in Tidewater and the Greater Richmond – Petersburg area.

In comparison to the James River Basin, the York River Basin is substantially smaller in size. This basin lies in the central and eastern section of Virginia and covers 2,674 square miles or 6% of the Commonwealth's total area. The headwaters of the York River begin in Orange County and flow in a southeasterly direction for approximately 220 miles to its mouth at the Chesapeake Bay. The York River is only approximately 30 miles in length and has only two major tributaries: the Pamunkey River (with the North and South Anna Rivers and the Little River as major tributaries) and the Mattaponi River (composed of the Matta, Po, and Ni Rivers).

Table 1: Major River Basins along the Study Area

Basin	HUC	General Drainage Direction	Approximate Watershed Boundary along the Project Corridor	Localities within the Project Corridor
Lower James	02080206	South	I-95 Interchange to Exit 227 (Toano)	City of Richmond, Henrico County, New Kent County, James City County
York	02080107	Northeast	Exit 227 (Toano) to Mile Marker 244 (just east of Exit 243, Busch Gardens)	James City County, York County
Lower James	02080206	South	Mile Marker 244 (just east of Exit 243, Busch Gardens) to Exit 255 (Jefferson Avenue)	York County, James City County, City of Newport News
Chesapeake Bay- Lynnhaven- Poquoson	02080108	North / East	Exit 255 (Jefferson Avenue) to I-664 Interchange	City of Newport News, City of Hampton

Lying in the Piedmont and Coastal Plain physiographic provinces, the York River Basin's topography is characterized by slightly rolling hills at the headwaters indicative of the Piedmont Physiographic Provide to the Coastal Plain Physiographic Province's gently sloping hills and flat farmland near its confluence with the Chesapeake Bay. Tributaries in the central Piedmont exhibit moderate and near constant profiles. Their flat slope largely characterizes streams in the Coastal Plain. Approximately 65% of the land area is forested. Farmland and pasture account for approximately 20% of the land area. Approximately 10% of the river basin land area is urban. The only major city that falls within this basin is a section of Williamsburg.

The Chesapeake Bay/Atlantic Ocean and Small Coastal Basins are located in the eastern part of Virginia and covers 3,592 square miles or approximately 8% of the Commonwealth's total land area. The combined basins encompass, in addition to the Bay itself, the small bays, river inlets, islands and shoreline immediately surrounding the Chesapeake Bay and the southern portion of the Delmarva Peninsula.

The topography of the Chesapeake Bay/Atlantic Ocean and Small Coastal Basin has little variation. The entire basin lies within the Coastal Plain Physiographic Province where elevations average no more than a few feet above sea level. More substantial elevation occurs along the central spine of the Eastern Shore portion, which forms a plateau about 45 feet above sea level. Much of the Chesapeake Bay/Coastal Basin

is marshland. About 30% of the Chesapeake Bay/Atlantic Ocean and Small Coastal Basin is forested, while nearly 22% is in cropland and pasture. Approximately 24% is considered urban.

Tributaries in the Chesapeake Bay/Atlantic Ocean and Small Coastal Basins drain into the Chesapeake Bay or the Atlantic Ocean. Major tributaries flowing into the Chesapeake Bay from the western shore are the Great Wicomico River, Piankatank River, Fleets Bay, Mobjack Bay including the East, North, Ware, and Severn Rivers, Poquoson River, Back River and Lynnhaven River.

A number of non-tidal and tidal surface water systems (including both wetlands and stream channels) are located along the study area corridor. These waters are detailed in the sections below. These systems have been identified both north and south of the mainline, as well as, within the median. Systems were also identified within and adjacent to a number of the interchanges. Stream channel types include perennial, intermittent, and ephemeral systems.

Major rivers along the study area corridor include the Shockhoe Creek, Chickahominy River, Boar Swamp, Rumley Marsh, Diascund Creek, Beaverdam Creek, Wahrani Swamp, Queen Creek, and Newmarket Creek. Numerous smaller tributary drainages to these major systems cross the study area.

2. Navigable Waters of the United States (Section 10 Waters) Methodology and Existing Conditions

Navigable Waters of the United States are regulated by the United States Army Corps of Engineers (Corps) under Section 10 of the Rivers and Harbors Act of 1899. The Corps general definition of navigable waters of the United States is "those waters subject to the ebb and flow of the tide shoreward to the mean high water mark and/or are presently used, or have been used in the past, or may be susceptible for use to transport interstate or foreign commerce. A determination of navigability, once made, applies laterally over the entire surface of the waterbody, and is not extinguished by later actions or events which impede or destroy navigable capacity." This includes, by definition, all tidal waterbodies including streams/ rivers and wetlands.

According to both the Navigable Waters of the United States Section 10 of the Rivers and Harbor Act list (Norfolk District Corps, March 5, 2010) and the United States Department of Transportation (USDOT) National Transportation Atlas Database (Version 11), there are no navigable waters identified within the study area corridor. However, neither of these sources includes tidal features in their database. The Corps, by definition, considers all tidal systems as navigable. The tidal features along the study area corridor are detailed in Section D.3 below, and include the channels (4,467 linear feet) and associated wetland systems (29.53 acres) of Queen Creek and Newmarket Creek.

Potential Impacts and Mitigation Measures

No-Build Alternative

The No-Build Alternative would not involve any project-related construction or changes to the natural environment. As a result, project-related impacts to navigable waters from the No-Build Alternative are not anticipated.

Build Alternatives

In accordance with the federal and state regulations governing streams and wetlands, efforts have been made to reduce the potential for impacts to navigable waters, wherever possible. However, because the Build Alternatives involve the widening of an existing corridor which currently crosses Queen Creek and Newmarket Creek (and the associated wetlands) impacts are unavoidable. **Table 2** summarizes the potential impacts to navigable waters associated with the different Build Alternatives. The potential impacts to both streams and wetlands are very similar for all Build Alternatives.

The values listed in **Table 2** represent an overlay of each Build Alternative's construction footprint. The existing crossings over Queen Creek and Newmarket Creek are span bridges. Therefore, the true footprint of the impact would be minimized due to the widening of these existing bridges. Additional discussion of the tidal waters and avoidance and minimization and compensatory mitigation measures for navigable waters (tidal systems) for this study are detailed in Section D.3.

Table 2: Potential Impacts to Navigable Waters of the United States

	Tidal				
Build Alternative	E2EM1P Wetlands (acres)	Other Waters of the United States (linear feet)			
Alternatives 1A/2A	28.01	3,012			
Alternatives 1B/2B	27.76	2,932			
Alternative 3	27.83	2,936			

3. Waters of the United States (Section 404/Section 401)

Methodology and Existing Conditions

All surface waters, including streams, lakes, ponds, and wetlands are protected and regulated by both the Corps and the Virginia Department of Environmental Quality (VDEQ) through Sections 404 and 401, respectively, of the Clean Water Act (CWA). These systems are collectively referred to as Waters of the United States (WUS), and refer to water bodies such as streams, rivers, wetlands, reservoirs, etc. The VDEQ also regulates these resources through the Virginia Water Protection Permit (VWPP) Program Regulation 9 VAC 25-210. In addition, in Virginia the Virginia Marine Resources Commission (VMRC) has jurisdiction over subaqueous bottoms or bottomlands, tidal wetlands, and coastal primary sand dunes through the Virginia Wetlands Act (Chapter 13, Title 28.2 of the Code of Virginia). This agency specifically regulates physical encroachment in, on, or over these resources.

The assessment methodology to identify the presence and location of WUS, including wetlands, within the study area corridor included both desktop and field review components. The desktop component involved the review of the United States Fish and Wildlife Service (USFWS) National Wetlands Inventory (NWI) maps and USGS 7.5-minute topographic quadrangles to identify perennial and intermittent streams subject to the regulations, Resource Protection Area (RPA) maps, hydrologic soils mapping, and natural color aerial imagery.

A surface water assessment was completed along the corridor in June, July, November and December of 2011 and March 2012. The field review was completed in areas which could be accessed within the study area corridor as depicted in the mapping in **Appendix C**. For sites where the areas could not be accessed due to fencing or landowner limitations, mapping of systems was conducted using the desktop review. Surface waters were designated as either a wetland (labeled WET) or other WUS (labeled WUS). The systems were further designated as being located north of the mainline ("N"), south of the mainline ("S"), or within the median ("M"). The same physical stream channel or wetland system may have different designations if they are located within more than one area (north or south of the mainline and/or within the median).

Wetlands were identified in the field in accordance with the *Corps of Engineers Wetland Delineation Manual* (Environmental Laboratory 1987) and supplemental guidance papers issued by the Corps, the NRCS, and the USFWS. This method requires the positive identification of three wetland parameters

during normal circumstances: hydrophytic vegetation, hydric soils, and wetland hydrology. After identification in the field, wetlands were then classified according to the Cowardin System, as described in *A Classification of Wetlands and Deepwater Habitats of the United States* (Cowardin et al. 1979). Regional supplements were not followed and Rapanos forms were not completed as part of this study's scope of work. The supplements were not followed to maintain consistency with earlier work conducted by VDOT staff. The boundaries of the systems were mapped using Global Positioning System (GPS) and identified on project base mapping. Wetland data sheets and Unified Stream Methodology (USM) Form 1s were completed for representative systems (N, S, and M) along the corridor. The wetland data sheets and USM Forms are included in **Appendix D**. Tables summarizing various characteristics of each system are included in **Appendix E**. Road side ditches (some jurisdictional and others non-jurisdictional) were common along the corridor and were assessed following guidance provided by the Corps and VDEQ, both in written communication and in personal communication during a pre-field work site visit held with the Corps on June 8, 2011. The procedures for completing the wetland and stream assessment, including not using the regional supplement and the approach to address stormwater management features were discussed with and agreed to by the Corps during the June 8, 2011 meeting.

On August 17, 2011, an on-site meeting was held with the Corps to review representative identified wetland and other WUS areas along the study area corridor. A formal jurisdictional determination was not completed at this point in time as part of the study scope of work. Therefore, all linear footage and acreage estimates within this report referencing jurisdictional features are subject to verification by the Corps.

Uplands tend to be graded down to the road level. Fill material was generally identified near stream crossings / bridges throughout the study area corridor. At the eastern end of the corridor due to the low elevation and generally flat terrain the existing highway was constructed on fill to promote drainage and limit flooding. Where the median has not been graded or is now concreted, drainage ditches line both sides of the eastbound and westbound lanes. Some of these drainage ditches were considered as potentially jurisdictional while others were not. East of the Lee Hall/Newport News Reservoir, drainage ditches (many jurisdictional pending determination by the Corps) and sound barriers are common, which have added to the altering of the natural systems.

A number of both stream and wetland systems were identified within and surrounding the interchanges, north and south of the mainline and within the median. Many of the stream systems are unnamed tributaries to the major systems along the corridor. In addition, a number of the streams and wetlands appear to have developed as a result of the original roadway construction, and the consequent drainage and other factors associated with the roadway. As well, many of the larger rivers/stream and wetland systems are currently spanned by bridges. All identified systems (subject to the Corps jurisdictional determination) are show on the mapping in **Appendix C**.

A total of 99.93 acres of wetlands and 148,493 linear feet of other WUS were identified within the study area corridor. The acreage and linear footage of tidal and non-tidal resources are summarized in **Table 3**. A total of 70.40 acres of non-tidal and 29.53 acres of tidal wetlands were identified. The tidal wetlands were associated with Queen Creek and Newmarket Creek. These two stream systems were the only tidal streams identified within the study area (4,467 linear feet). Considering non-tidal stream systems, 127,563 linear feet of perennial channel, 12,490 linear feet of intermittent channel, and 3,800 linear feet of ephemeral channel were identified within the study area. In addition, 173 linear feet of lacustrine resources were identified.

Table 3: Identified Wetlands and Other Waters of the United States within the Study Area

Resource	Wetlands (acres)	Other Waters of the United States (linear feet)
Total Identified Resources	99.93	148,493
Non-Tidal Systems	70.40	144,026
Tidal Systems	29.53	4,467

Bridges with pier supports currently span the tidal systems, in addition to many of the larger, non-tidal resources. Any improvements along these areas would include the widening of the existing bridges, limiting the potential permanent impacts to primarily impacts associated with pier work.

As summarized in **Tables 4, 5, and 6**, the median had the least amount of both wetlands and other WUS. The greatest amount of wetlands and greatest amount of other WUS were identified south and north of the mainline, respectively. Regarding tidal features, the least amount of resources were identified within the median (0.66 acres of wetlands and 98 linear feet of other waters), the greatest amount of wetlands (21.73 acres) were identified south of the mainline, and the greatest amount of other WUS (4,249 linear feet) was located north of the mainline. Tables summarizing the quantity of impact for each stream and wetland system located within the study area are included in **Appendix F.**

Table 4: Location of Identified Wetlands and Other Waters of the United States within the Study

Area

Location	Wetlands (acres)	Other Waters of the United States (linear feet)
North of Mainline	35.80	66,370
Median	18.09	19,275
South of Mainline	46.04	62,848

Table 5: Wetlands Identified within the Study Area

Classification	Acreage Located North of the Mainline	Acreage Located within the Median	Acreage Located South of the Mainline	Total Acreage
E2EM1P	7.14	0.66	21.73	29.53

PFO	14.32	17.15	11.11	42.58
			Grand Total	99.93

Palustrine systems are all non-tidal wetlands dominated by trees, shrubs, and persistent emergent herbaceous plants. Palustrine forested wetlands (PFO) were the most common types of wetlands identified within the study area (42.58 acres). These types of systems are non-tidal wetlands

characterized by the domination of woody vegetation greater than 20 feet in height with greater than 30% canopy cover. Many of these systems typically have an overstory of trees with an understory of young trees and shrubs and an herbaceous layer. All water regimes are potentially present, except subtidal and permanently flooded, are included. Estuarine intertidal emergent wetlands (E2EM) associated with Newmarket Creek and Queen Creek were the second most common type identified (29.53 acres). This large value is primarily due to the wide study area around the I-664 interchange near Newmarket Creek. These systems include deepwater tidal habitats and adjacent tidal wetlands that are usually semi-enclosed by land but have open, partly obstructed, or sporadic access to the ocean, with ocean-derived water at least occasionally diluted by freshwater runoff from the land. The upstream and landward limit is where ocean-derived salts measure less than 0.5 ppt during the period of average annual low flow.

Approximately 23.10 acres of palustrine emergent wetlands (PEM) were the identified within the study area. These non-tidal wetlands are characterized by erect, rooted, herbaceous hydrophytes, excluding mosses and lichens. This vegetation is present for most of the growing season in most years, and the systems are typically dominated by perennial plants. There is a variety of water regimes that influence the soil, vegetation and habitat characteristics. Palustrine scrub shrub wetlands (PSS) were the least common along the study corridor (4.72 acres). This non-tidal wetland type is generally defined by greater than 30% canopy cover of shrubs or small trees less than 20 feet in height. Plant species typically include true shrubs, young trees, and trees or shrubs that are small or stunted due to environmental conditions. All water regimes except subtidal and permanently flooded are potentially included in this system type.

Table 6: Other Waters of the United States Identified within the Study Area

Classification	North of the Mainline Linear Feet Located within the Med		Linear Feet Located South of the Mainline	Total Linear Feet
Ephemeral	326	682	2,792	3,800

R4UB3 (Non-tidal Intermittent)	67	0	0	67
			Grand Total	148,493

Non-tidal perennial stream systems were the most common types of other WUS (127,563 linear feet) identified within the study area. A perennial stream is a system which has constant flow at all times with the possible exception of times of extreme drought. Non-tidal intermittent channels were the second most common other WUS identified (12,490 linear feet). An intermittent channel is defined as a system with flow varying based on a number of factors including groundwater table and the discharge from feeder systems. Approximately 4,467 linear feet of tidal systems were identified along Newmarket Creek and Queen Creek. These systems are influenced by the ebb and flow of the ocean tides. Ephemeral channels are those channels which are not influenced by the groundwater table but only have water flowing through them as the direct response to recent and local precipitation. Approximately 3,800 linear feet of ephemeral channels were identified within the study area. Approximately 173 linear feet of lacustrine system, associated with the Newport News/Lee Hall Reservoir were identities within the study area. Lacustrine systems are those systems which include area of open water greater than 20 acres or more that are 6.6 feet in depth. A number of jurisdictional ditches (pending determination by the Corps) were identified along the corridor. These systems included WUS 6N, WUS 7N, WUS 8N, WUS 10N, and WUS 13N.

The USM is a collaborative effort between the Corps (Norfolk District) and the VDEQ. The USM is a method to simply assess characteristics of a potentially impacted stream and determine the required compensatory mitigation for that system based, in part, on the impact type (e.g., filling, culverts, etc.). The USM is a four part process consisting of the following: 1) assign a Reach Condition Index (RCI) to the stream to be impacted; 2) assess the type or severity of impact; 3) determine the compensation requirement; and, 4) determine what types of and the amount of the various compensation practices that would satisfy the compensation requirement. To determine the RCI, the condition of the channel is assessed for the following four characteristics: channel condition, riparian buffer, in-stream habitat, and channel alteration. In following the USM, RCI scores can range from 0 (lowest condition) to 1.5 (highest condition).

For this study, representative stream channels were assessed using the USM to determine the RCI for that specific reach. Required compensatory mitigation requirements can not be determined at this time as the specific impact type and linear footages are not available. This determination would be completed as part of the permitting process for the project. The RCI scores for the assessed channels ranged from 0.5 (an ephemeral channel) to 1.5 (the Chickahominy River). The USM Form 1s are included in **Appendix D**. The RCI values for the assessed resources are included in the summary table in **Appendix E**.

The majority of both wetland and other WUS systems have been influenced to some degree by the roadway itself or the intense development along the corridor, particularly those systems in or near the Cities of Richmond, Newport News, and Hampton. Many of the systems have been heavily manipulated through past ditching or filling activities associated with the road development and previous improvements. In addition, a number of the channels appear to have developed from drainage from the roadway and a number of wetland systems appear to have developed through constraints associated with and drainage to the interchanges and median. Despite the high degree of previous disturbance, these systems may still provide ecological functions such as wildlife habitat, flood control, and water quality benefits such as nutrient uptake and sediment trapping.

Potential Impacts and Mitigation Measures

No-Build Alternative

The No-Build Alternative would not involve any project-related construction or changes to the natural environment. As a result, project-related environmental effects from the No-Build Alternative are not anticipated.

Build Alternatives

In accordance with the federal and state regulations governing streams and wetlands, efforts have been made to reduce the potential for impacts to jurisdictional WUS, including wetlands, wherever possible. However, because this study involves the widening of an existing corridor which currently crosses numerous stream and wetland systems, impacts are unavoidable. In addition, along the greatest areas of impacts and in areas where bridges already exist, the true footprint of the impact would be minimized due to the widening of the existing bridges. In these cases, the potential activity in surface waters may simply result from the installation of piers. Also, in many cases the impacts are the result of culvert extensions and not complete fill of the system itself. In addition, since the construction area for all Build Alternatives is similar, the difference in total impacts among the Alternatives is similar.

Tables 7, 8, and 9 summarize the potential impacts resulting from each Build Alternative to WUS, including wetlands, along the study area corridor. As shown below, the overall impacts associated with Build Alternatives are very similar. While all Build Alternatives result in very similar overall impacts, the highest amount of both wetland and stream channel tidal impacts would occur from Build Alternatives 1A/2A. The wetland acreages and stream linear footages listed in all summary tables in Section D represent the values associated with an overlay of each Build Alternative's construction footprint.

The mitigation measures for stream and wetland impacts would be identified for the Preferred Alternative during final design. These measures would include avoidance and minimization efforts to the greatest extent practicable. Some measures which may be considered include: the use and appropriate placement of erosion and sediment control measures and best management practices; the use of upgraded erosion and sediment controls in environmentally sensitive areas; bridging/spanning of streams and wetlands; alignment shifts around specific systems; the use of cofferdams; steepening of slopes and the use of retaining walls on steeper slopes; properly countersunk culverts; stream relocation to improve skew angle and shorten culverts if new culverts are necessary; and ensuring groundwater recharge/wetland hydrology maintenance through the location of outfalls and infiltration trenches. Following construction practices, any additional stormwater generated through new impervious surfaces would be treated through improved stormwater management systems.

Coordination with the Corps, VDEQ, and VMRC would be required during the permitting phase of the project to determine the jurisdictional limits of surface waters and to make a final determination of the need for and type of permits. Both temporary and permanent effects to jurisdictional wetland and stream systems from any of the Build Alternatives would require a permitting decision from these agencies. Based on the scale of the project, the multiple individual impact area crossings and the potential for tidal impacts it is anticipated that a Section 404 Individual Permit from the Corps, a Virginia Water Protection (VWP) Individual Permit from the VDEQ, and a Subaqueous Bottomlands Permit from the VMRC would be required. For VDOT projects, VMRC issues the VGP-1 permit for subaqueous bottom encroachments where the drainage area of the impact zone(s) exceeds five square miles. Wetland impacts are exempted for the State.

Compensatory mitigation would likely be required for permanent impacts to stream and wetlands resulting from the construction activities. Compensatory mitigation is typically required in the same or adjacent HUC within the same watershed and physiographic province as the impact. As part of the permitting process, mitigation options would be investigated using the various agency resources including the July 2004 Joint Corps and VDEQ *Recommendations for Wetland Compensatory Mitigation: Including Site Design, Permit Conditions, Performance Criteria, and Monitoring Criteria* and the associated *Mitigation Checklist*, as well as the March 2008 Offsite Mitigation Guidelines. Of greatest significance, on April 10, 2008, new regulations providing guidance for compensatory mitigation was jointly issued by the Corps and USEPA. The new mitigation rule, which became effective June 9, 2008, changed the federal permitting preference regarding how compensatory mitigation is accomplished for project impacts to jurisdictional surface waters. This rule does not change when compensation is required.

The new rule provides the following preference for compensatory mitigation options:

- 1. Purchase of compensatory mitigation bank credits.
- 2. Purchase of an approved in-lieu fee fund credits.
- 3. Watershed approach based mitigation by the permittee.
- 4. On-site mitigation/in-kind mitigation by the permittee.
- 5. Off-site mitigation/out-of-kind mitigation by the permittee.

Both the Corps and VDEQ have currently adopted this hierarchy of compensatory mitigation options for permanent impacts to jurisdictional surface waters. There are currently a number of compensatory mitigation banks that have the appropriate available credits for the potential impacts. The final compensatory mitigation option would be determined during the project's permitting process.

In addition, the compensatory mitigation requirements for both streams and wetlands would be determined for the selected Build Alternative during the permitting phase. The current typical compensatory mitigation to impact ratios for non-tidal forested, scrub-shrub, and emergent wetlands are 2:1, 1.5:1, and 1:1, respectively. The compensatory mitigation to impact ratio for tidal emergent wetlands

is determined on a case-by-case basis; however, 2:1 is typical for these systems. The approved assessment methodology to determine the required stream compensation would be completed as part of the compensatory mitigation plan. As detailed above, at the time of this document, the approved assessment methodology is the USM. All potentially impacted channels would need to be assessed and the USM methodology completed in full to determine the compensatory mitigation requirements for the project. Compensatory mitigation for tidal stream systems would be determined on a case-by-case basis. Compensatory mitigation is typically required for unavoidable stream impacts to greater than 300 linear feet of stream at a crossing. However, this determination would be made on a project-by-project basis and due to the scale of this specific project, this threshold may be waived. At this time, compensatory mitigation is not typically required for impacts to jurisdictional ditches. The requirements for compensation for jurisdictional ditch impacts would be determined during the permitting process. Compensatory mitigation is not typically required for open water impacts (e.g., piers in open waters) but this requirement would be reviewed on a case-by-case basis.

In accordance with the existing regulations and standard permit conditions, all temporary impacts would also be required to be restored to their original contours and re-vegetated with the same or similar species. Additional compensatory mitigation other than previously stated for temporary impacts is typically not required through the permitting process.

E. Water Quality

Methodology and Existing Conditions

State and federal law requires VDEQ to report to the USEPA, as well as the local citizens, the condition of the Commonwealth's water systems. Section 305(b) of the CWA requires each state to submit a biennial report to USEPA describing the quality of its navigable waters. The 305(b) report provides VDEQ's best overall assessment of water quality conditions in the State. The 305(b) process assesses six primary designated uses (identified below), as appropriate for a particular waterbody, based on the regulatory Water Quality Standards. These primary uses are further broken into sub-categories.

- Aquatic Life Use supports the propagation, growth, and protection of a balanced indigenous
 population of aquatic life which may be expected to inhabit a waterbody. In Chesapeake Bay
 waters (mainstem and tributaries), this use is divided into sub-uses that target specific aquatic life
 assemblages.
- Recreation Use supports swimming, boating, and other recreational activities.
- Fish Consumption Use supports game and marketable fish species that are safe for human health.
- Shellfishing Use supports the propagation and marketability of shellfish (clams, oysters, and mussels).
- Public Water Supply Use supports safe drinking water.
- Wildlife Use supports the propagation, growth, and protection of associated wildlife.

Virginia's Water Quality Standards define the water quality needed to support each of these uses by establishing the numeric criteria that physical and chemical data are assessed against. If a waterbody contains more of a pollutant than is allowed by the Water Quality Standards, it would not support one or more of its designated uses as described above. Such waters are considered to have an "impaired" quality. According to the State, "impairment" refers to an individual parameter or characteristic that

violates a Water Quality Standard. A system fails to support a designated use when it has one or more impairments.

To determine if the designated uses are being met, the VDEQ tests, or obtains data for, selected water systems (including rivers, lakes and tidal waters) for pollutants at more than 1,000 locations across the Commonwealth on an annual basis. The samples are tested for over 130 contaminants including levels of nutrients, solids, bacteria associated with human and animal wastes, toxic metals, some pesticides and harmful organic compounds. Field tests are also performed for dissolved oxygen, pH, temperature, salinity, and additional indications of water quality. Sediment samples are tested for the presence of pesticides and other harmful compounds including levels of nutrients, solids, bacteria associated with human and animal wastes, toxic metals, some pesticides and harmful organic compounds. Waters that do not meet standards are reported to the citizens of Virginia and the USEPA in *Virginia Water Quality Assessment 305(b)/303(d) Integrated Report*.

VDEQ has developed this impaired waters list in even years since 1992. The impaired waters list describes segments of streams, lakes and estuaries that exhibit violations of Water Quality Standards. The report details the pollutant responsible for the violations, and the suspected cause and source of the pollutant. All anthropogenically impaired waters in Virginia are placed on a federally mandated 303(d) impaired waters list. Waters that are impaired due to human activities require a plan to restore water quality and associated designated use(s). VDEQ schedules each of these waters for development of a Total Maximum Daily Load (TMDL), which is a reduction plan that defines the limit of a pollutant(s) that a water can receive and still meet water quality standards. A TMDL Implementation Plan is developed after a TMDL is approved by USEPA. Once fully implemented, the TMDL Implementation Plan would restore the impaired waters and maintain its water quality.

The type of water quality data or parameters collected is determined by the waterbody's classification and corresponding Water Quality Standards. The information gathered from the monitoring stations determines the "use support" status of waterbodies, or how well a waterbody supports its designated uses. The categories are divided into the following categories based on USEPA guidelines. VDEQ has included sub-categories to these federally mandated categories, as described in the "impaired waters" Categories 4 and 5 below.

- Category 1 Waters support one or more designated uses.
- Category 2 Available data and/or other information indicate that some, but not all of the designated uses are supported.
- Category 3 Insufficient data and/or information to determine whether any designated uses are met.
- Category 4 Waters are impaired or threatened but do not need a TMDL.
 - USEPA Category 4A water is impaired or threatened for one or more designated uses but does not require a TMDL because the TMDL for specific pollutant(s) is completed and USEPA approved.
 - USEPA Category 4B water is impaired or threatened for one or more designated uses but does not require the development of a TMDL because other pollution control requirements (such as VPDES limits under a compliance schedule) are reasonably expected to result in attainment of the Water Quality Standard by the next reporting period or permit cycle.

- USEPA Category 4C water is impaired or threatened for one or more designated uses but does not require a TMDL because the impairment is not caused by a pollutant and/or is determined to be caused by natural conditions.
- Category 5 Waters are impaired and do need a TMDL.
 - Virginia Category 5A a Water Quality Standard is not attained. The water is impaired or threatened for one or more designated uses by a pollutant(s) and requires a TMDL (303d list).
 - Virginia Category 5B the Water Quality Standard for shellfish use is not attained. One or more pollutants causing impairment require TMDL development.
 - Virginia Category 5C the Water Quality Standard is not attained due to "suspected" natural conditions. The water is impaired for one or more designated uses by a pollutant(s) and may require a TMDL (303d list). Water Quality Standards for these waters may be re-evaluated due to the presence of natural conditions.
 - Virginia Category 5D the Water Quality Standard is not attained where TMDLs for a pollutant(s) have been developed but one or more pollutants are still causing impairment requiring additional TMDL development.
 - Virginia Category 5E effluent limited facilities are not expected to meet compliance schedules by next permit cycle or reporting period.

The VDEQ released the *Final 2010 305(b)/303(d) Water Quality Assessment Integrated Report* (Integrated Report) on February 9, 2011. The 2010 Integrated Report is a summary of the water quality conditions in Virginia from January 1, 2003 through December 31, 2008.

As previously detailed, the study area corridor falls within three of the twelve major river basins in Virginia: the James River (Lower sub-basin), the York River, and the Chesapeake Bay/Atlantic and Small Coastal Basins. A number of stream systems and other waterbodies, including reservoirs, in the vicinity of and draining from the study area have been listed as impaired in the 2010 Integrated Report. As summarized in **Table 16**, of those listed, nine surface waters that fall within the study area corridor have been listed as impaired (Categories 4 and/or 5) waters. In addition, according to the 2010 Integrated Report, a number of the systems and tributaries both within and in the vicinity of the study area corridor are under Virginia Department of Health (VDH) Fish Consumption Advisories. These advisories result from elevated levels above the state standards for the listed contaminant potentially associated with human health concerns.

Of these nine Category 4 or 5 waters, the Cause Categories for these waters were identified as 4A, 5A, or 5C. According to the 2010 Integrated Report, a Category 4A water is a water that is impaired or threatened for one or more designated uses but does not require a TMDL because the TMDL for specific pollutant(s) is completed and USEPA approved. In addition, all Category 5 waters are considered impaired and likely needing a TMDL. While waters categorized as 5A, 5B, or 5D in the 2010 Impaired Waters List are waters that VDEQ believes need a TMDL study, Category 5C waters are believed to be impaired due to natural conditions, and further study of each water are needed to determine if a TMDL is applicable or if changes to Water Quality Standards are appropriate to reflect those natural conditions. However, 5C waters are still listed with TMDL development dates in the Impaired Waters List.

		Shellfishing	4A	Fecal Coliform	

Six systems, including one reservoir, in the James River basin were listed as impaired in the 2010 Integrated Report. Gillies Creek, Stony Run and Diascund Creek have been placed on the 303(d) list with an impaired use for Recreation for *Escherichia coli*. The sources of the *Escherichia coli* impairments for the three systems are listed as "Unknown". However, Combined Sewer Overflows are also listed for this impairment in Gillies Creek. Rumley Marsh, Diascund Creek, and Beaverdam Creek were all listed for Dissolved Oxygen (Recreation), with the source of this impairment stated as Natural Conditions – Water Quality Standards Use Attainability Analysis Needed. Levels of pH measured beyond the required standard were identified in Gillies Creek and Rumley Marsh, causing an impaired designated use for Aquatic Life. For Rumley Marsh, 2010 was the initial listing of this impaired use.

The Lee Hall Reservoir (also commonly referred to as the Newport News Reservoir) was listed for exceeding copper levels (for both the Aquatic Life and Wildlife designated uses). This impairment was initially listed for the reservoir in 2004. In addition, PCB and Mercury concentrations in the reservoir have exceeded state standards, resulting in the issuance of fish advisories from the VDH. This year (2010) was the first year these impairments have been listed for the reservoir. The reservoir was also listed for Dissolved Oxygen (Aquatic Life), with the initial listing for this impairment occurring in 2006. The source(s) of all the impairments for the reservoir are listed as "Unknown" in the 2010 Integrated Report.

Queen Creek, the only listed watercourse along the corridor in the York River Basin, was listed for *Enterococcus* (Recreation), Shellfishing (Fecal Coliform), Aquatic Life/Open-Water Aquatic Life (Dissolved Oxygen) and Aquatic Life/Shallow-Water Submerged Aquatic Vegetation (SAV) (Aquatic Plants [Macrophytes]). In addition, Queen Creek has posted a PCB Fish Consumption advisory based on the assessment activities. All source(s) of impairments are listed as "Unknown" with the exception of the Aquatic Life/Shallow-Water SAV designated use. These listed sources include Non-Point Source and Point Source and Combination of Stormwater Wet Weather Discharges, Industrial and Municipal Point Source Discharges, Loss of Riparian Habitat, Atmospheric Deposition of Nitrogen, Internal Nutrient Recycling; Agricultural Practices, Sediment Resuspension (Clean Sediment) and Sources Outside the state Jurisdiction or Borders. This system was initially listed in 1998 for 1998 (Shellfishing – Fecal Coliform). There are no new listed impairments in 2010.

In the Chesapeake Bay/Atlantic/Small Coastal Basins, both the upper and lower sections of Newmarket Creek have been listed for Aquatic Life/Open-Water Aquatic Life (Dissolved Oxygen), Aquatic Life/Shallow-Water SAV (Aquatic Plants [Macrophytes]), Recreation (*Enterococcus*), Shellfishing (Fecal Coliform), and Fish Consumption (PCB in Fish Tissue). The source(s) of the PCB in Fish Tissue and *Enterococcus* are listed as "Unknown". Sources for the Dissolved Oxygen and Aquatic Plants (Macrophytes) impairment are listed in the report and include Non-Point Source and Point Source and Combination of Stormwater Wet Weather Discharges, Loss of Riparian Habitat, Municipal and Industrial Point Source Discharges, Atmospheric Deposition of Nitrogen, Internal Nutrient Recycling, Agricultural Practices, and Sources Outside the State Jurisdiction or Borders. For both sections of Newmarket Creek, the systems were originally listed in 1998 (for Shellfishing - Fecal Coliform), and there were no new listed impairments in 2010.

A table providing a detailed summary, including the water name and location, designated use, cause group code, category and name, source of pollutant(s), date of initial listing, and TMDL schedule of the impaired waters (Categories 4 and 5) located within the study area corridor is included in **Appendix G**. These systems, as well as systems in the vicinity of the study area, are also depicted on the mapping included in **Appendix H**.

Potential Impacts and Mitigation Measures

No-Build Alternative

The No-Build Alternative would not involve any project-related construction or changes to the natural environment. As a result, project-related environmental effects from the No-Build Alternative are not anticipated.

Build Alternatives

All of the Build Alternatives have the potential to increase levels of certain contaminants within the affected surface waters. These increases would be expected to be minimized with the use of approved sediment and erosion control during construction and implementation of stormwater best management practices. However the Build Alternatives could still affect water quality to some degree, exacerbating problems within sub-watersheds where contaminant levels are already elevated.

Potential impacts during construction could include physical disturbances or alterations, accidental spills, and sediment releases that can affect aquatic life. During construction, wind and rain could severely erode large areas of soil exposed following the removal of vegetation, considerably increasing sediment load to receiving waters. While all of the Build Alternatives have the post-construction potential to affect existing surface waters to a degree, the relatively small amount of new impervious surfaces and related pollutants that the project would add, in addition to the improved stormwater management practices, would be expected to cause only minimal changes, if any, to the corridor water quality.

A number of the surface waters listed as "impaired" are designated, at least in part, due to *Escherichia coli, Enterococcus*, and Fecal Coliform. These parameters, in addition to PCB, Mercury, and Copper contamination, would not be affected by highway construction. Another major parameter of impairment in the listed streams is Dissolved Oxygen. Since Dissolved Oxygen concentrations can become adversely low following algal blooms resulting from nutrient loading, any use of nutrient-rich fertilizers or excessive stormwater discharges resulting from the road project could contribute to impairment of the systems. This could also lead to elevated levels of pH, which were causes of contamination in Gillies Creek and Rumley Marsh. The failure to meet the Designated Use for Aquatic Life/Shallow-Water SAV in Newmarket Creek (both the lower and upper sections) and Queen Creek may be increased through the roadway project due to nutrient loading or excessive stormwater discharges (as noted above) and through excessive clearing of existing vegetation.

After construction, impacts associated with the use of the roadway would be primarily based on the potential for contamination of surface waters by runoff from new impervious surfaces. These runoff constituents would likely include heavy metals, salt and associated materials, organic molecules, and nutrients. However, this runoff would be treated by improved stormwater management facilities. Therefore, potential impacts are expected to be minimal, if any.

As part of the construction practices, minimizing or restricting the use of nutrient-bearing (phosphorus and nitrogen) fertilizers, following the proper application of the appropriate fertilizer and/or utilizing appropriate stormwater management facilities that effectively prohibit nutrient loading of receiving waters for the Alternative crossings may be considered, as appropriate. These practices should be implemented not just in the vicinity of streams impaired due to low Dissolved Oxygen, but to all systems to prevent the systems from being listed as impaired in the future. These control measures would also assist in off-setting impairment due to changes in pH and reduced SAV. In addition, clearing practices should be limited to the greatest extent possible to reduce potential for impairment to the systems. Based on the impairments listed, any crossing in the vicinity of a waterway may include stormwater management plans designed specifically to address the particular condition. During construction, all appropriate erosion and sediment control measures would be employed and although impervious surface would increase runoff post-construction, all stormwater would be treated through improved stormwater management facilities.

F. Surface and Groundwater Supply

Methodology and Existing Conditions

The Coastal Plain region in Virginia is composed mostly of unconsolidated deposits, primarily alternating layers of sand, gravel, shell rock, silt, and clay. These extremely permeable layers hold substantial amounts of groundwater. Therefore, the pollution potential in the uppermost unconfined aquifer within this area is very high due to the high permeability and high population density and agricultural activities in the area.

A large portion of Virginia's groundwater use in this region occurs in the two separate groundwater systems: one shallow, one deep. In many areas, a shallow unconfined aquifer system lies above

relatively impermeable clay beds and is the source of water for hundreds of domestic and other small capacity wells. The principal source of major groundwater withdrawals is a deeper system of confined aquifers. The recharge area to these aquifers occurs many miles away where the formations outcrop but infiltration from the water table and a shallower confined aquifer also recharge the deeper confined aquifers. This allows for the passage of pollutants to these deeper regions.

The natural water quality in the Coastal Plain aquifers is high except in areas where saltwater, iron, and hydrogen sulfide occurs. In aquifers near a salt water interface, salt water may migrate west as aquifers are pumped. As a result, water from the deep aquifers near the lower York-James Peninsula generally contains high chloride concentrations, requiring treatment for domestic use. According to the USGS, more than 125 million gallons of water are pumped every day from the aquifers, supplying roughly one million people.

The USEPA defines a sole source aquifer as one which supplies at least 50% of the drinking water consumed in the area overlying the aquifer. According to the USEPA Sole Source Aquifer Virtual Aquifer Map, no sole source aquifers, as defined under Section 1424(e) of the Safe Drinking Water Act, have been designated in the study area or the immediate vicinity. As summarized below, there are a number of reservoirs that provide the population's drinking water.

Under the Ground Water Management Act of 1992, the VDEQ manages groundwater through a program regulating the withdrawals in certain areas called Ground Water Management Areas (GWMA). Currently, there are two GWMAs in the State, including the Eastern Virginia GWMA which comprises the area east of I-95 and south of the Mattaponi and York Rivers. From the City of Richmond/Henrico County border to the study termini in the City of Hampton, the study area corridor lies within the Eastern Virginia GWMA. In accordance with the Ground Water Management Act, any person or entity wishing to withdraw 300,000 or more gallons of groundwater per month in the GWMA must obtain a permit from the VDEQ. However, this project would not involve any water withdrawals.

Seven reservoirs are located in the vicinity of the study area corridor, with the study area bisecting one (Lee Hall/Newport News Reservoir) and intersecting with the upstream limits of Diascund Creek Reservoir. Reservoir information was obtained from various sources, including locality Geographic Information System (GIS) data, communication with localities, locality government websites and Google maps. **Table 17** provides a summary of the reservoirs located in the vicinity of the study area corridor. The locations of these reservoirs are identified on various mapping in this document including **Figure 1** and the mapping in **Appendix C**.

Diascund Creek Reservoir is located in New Kent County south of the study area corridor, near Exit 220 (West Point). Drainage along the study area corridor from approximately the New Kent County line to the Exit 227 (Toano) is to the reservoir. Major stream systems (and their smaller tributaries) that cross the study area corridor and draining to this reservoir include Diascund Creek, Beaverdam Creek, Wahrani Swamp, and Barnes Swamp. Little Creek Reservoir is located in James City County south of the study area corridor, near Exit 231 (Croaker/Norge). Drainage along the study area corridor flows northeast, away from the Little Creek Reservoir. Although located in the two Counties, the water itself in both of these reservoirs is owned by the City of Newport News.

Waller Mill Reservoir, which is surrounded by Waller Mill Park and is the City of Williamsburg's major source of treated waters, is located in York County, south of the mainline, east of Exit 234 (Lightfoot). The reservoir was created by damming the upstream section of Queen Creek. Systems within the study area boundary along this area drain northeast, away from the reservoir.

Skiffes Creek Reservoir is located in the City of Newport News, just south of the mainline near Exit 247 (Yorktown). Drainage from the study area is to the reservoir. The corridor directly crosses the Lee Hall Reservoir (also referred to as the Newport News Reservoir) east of Mile Marker 294. This reservoir, which is formed from the damming of the Warwick River, is surrounded by the Newport News City Park and is an important source of drinking water for the Hampton Roads Peninsula. The Harwoods Mill Reservoir is located in the City of Newport News north of the study area corridor, near Exit 256 (Victory Boulevard). This 265 acre impoundment is the terminal reservoir for the City of Newport News water supply system. Water is pumped into Harwoods Mill from Chickahominy River, and the Diascund Creek and Little Creek Reservoirs. Drainage from the study area corridor flows away from this reservoir. Big Bethel Reservoir is located in York County and the City of Newport News, north of the mainline, near Exit 258 (J Clyde Morris Boulevard). Several systems drain from the study area corridor to this reservoir, including Brick Kiln Creek.

Table 17: Reservoirs in the Vicinity of the Study Area

	Table 17: Reservoirs in the vicinity of the	c Study Arca
Reservoir Name	Reservoir Location	Drainage Flow from the Study Area Corridor
Diascund Creek Reservoir	New Kent County (near Exit 220, West Point), south of the corridor	South to the reservoir; corridor bisects upstream limits of reservoir
Little Creek Reservoir	James City County (near Exit 231, Croaker/Norge); south of the corridor	Northeast away from the reservoir
Waller Mill Reservoir	York County (east of Exit 234, Lightfoot); south of the corridor	Northeast away from the reservoir
Skiffes Creek Reservoir	City of Newport News (near Exit 247, Yorktown), south of the corridor	South to the reservoir
Lee Hall Reservoir/Newport News Reservoir	City of Newport News (near mile marker 249)	Study area corridor directly crosses the reservoir
Harwoods Mill Reservoir	City of Newport News (near Exist 256, Victory Boulevard), north of the corridor	South away from the reservoir
Big Bethel Reservoir	York County and the City of Newport News (near Exit 258, J Clyde Morris Boulevard), north of the corridor	Northeast to the reservoir

The VDH - Office of Drinking Water reviews projects for the proximity of the site to public drinking water sources. Through the project scoping process, the VDH provided the following information related to the proximity of public drinking water sources (groundwater wells, springs, and surface water intakes) to the study area corridor.

According to information provided by VDH, for the seven groundwater sources identified in Zone 1 in **Table 18**, only one public groundwater source is located within 100 feet of the existing edge of pavement along the study area corridor. This public groundwater well is owned by New Kent Farms, and is located north of the westbound exit ramp at Exit 211 (Talleysville) in New Kent County. The approximate location of this well is included in **Figure 3**. In addition, of the surface water intakes noted in the **Table 19**, no public surface water intake is located within 100 feet of the existing edge of pavement along the study area corridor.

The Safe Drinking Water Act (SDWA), as amended in 1996, expanded the protection from groundwater based public water supply systems to all public water supply systems, including surface water. The SDWA also required an assessment to evaluate every public water supply system's vulnerability or susceptibility to contamination. The SDWA also required Virginia to develop a Source Water Assessment Program and to submit the plan to the USEPA. This amendment included Virginia adopting a one mile wellhead protection zone around all groundwater public sources. The VDH received USEPA approval for their plan and completed that assessments and susceptibility evaluations on all public water supply systems in the Commonwealth in 2006.

According to the VDH-Office of Drinking Water, they do not manage or administer designated wellhead protection zones along the study area corridor. In addition, according to VDH, of the seven localities along the corridor, only New Kent County and James City County have water supply protection plans; however, they do not have designated protection zones.

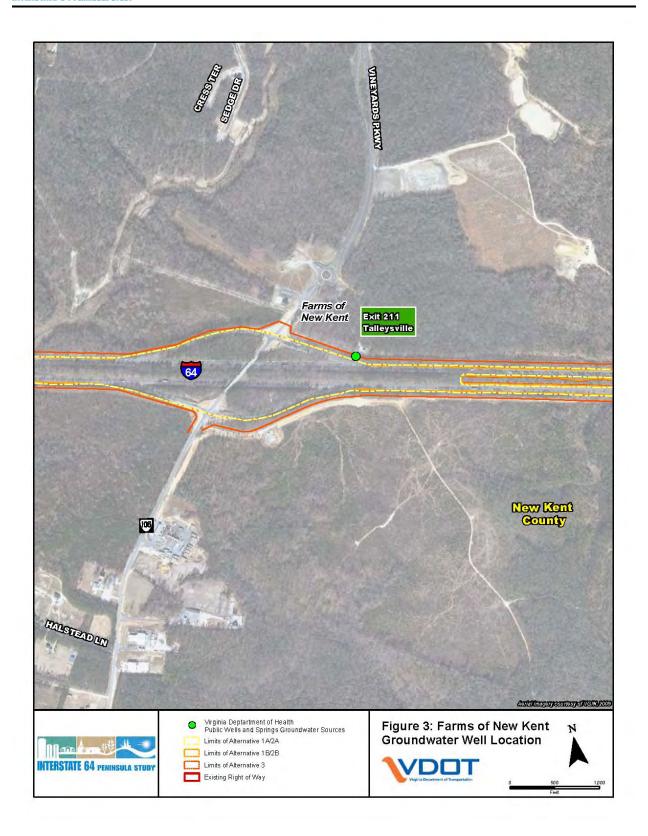

Table 18: VDH Groundwater Sources within the Study Localities

Location	City of Richmond	Henrico County	New Kent County	James City County	York County	City of Newport News	Total Wells
Zone 1 (wells within 1,000 feet)	0	0	3	3	1	0	7
Zone 2 (wells within 1 mile)	0	0	16	13	8	4	41
Total Wells in Locality	0	0	19	16	9	4	48

Zone 2 (intake >5 miles into watershed)	0	0	1	1	0	0	2
Total Surface Water Intakes in Locality	0	0	2	1	2	2	7

Potential Impacts and Mitigation Measures

No-Build Alternative

The No-Build Alternative would not involve any project-related construction or changes to the natural environment. As a result, project-related environmental effects from the No-Build Alternative to either the groundwater or surface water resources are not anticipated.

Build Alternatives

Surface Waters

All of the Build Alternatives have the potential to increase levels of contaminants within the affected surface waters draining to the reservoirs. The four reservoirs either crossed by or receiving drainage from the study area corridor include Diascund Creek Reservoir, Skiffes Creek Reservoir, Lee Hall Reservoir/Newport News Reservoir, and Big Bethel Reservoir. The increases in contaminants would be expected to be minimized with the use of both the appropriate sediment and erosion control during construction and the implementation of best management practices.

Potential impacts during construction could include physical disturbances or alterations, accidental spills, and sediment releases that can affect aquatic life and water quality are potential impacts that could occur during construction activities. During construction, wind and rain could severely erode large areas of exposed soil, either through the removal of existing vegetation or staged stockpiles. This erosion could lead to an increased sediment load to surrounding surface waters. While all the Build Alternatives have the potential to affect existing surface waters to a degree, the relatively small amount of new impervious surfaces and related pollutants that the project would add, in addition to improved stormwater treatment facilities, would be expected to cause no or only minimal changes to the water quality of the surface waters surrounding the study area corridor.

Impacts associated with the use of the roadway following construction would be primarily based on the potential for contamination of surface waters by runoff from new impervious surfaces. These runoff constituents would likely include heavy metals, salt and associated materials, organic molecules, and nutrients. However, this runoff should be treated by improved stormwater management facilities. Therefore, potential impacts to the receiving waters are expected to be minimal, if any.

During construction, the potential for impacts to the reservoirs would be minimized through strict adherence to the required appropriate erosion and sediment control practices, which include best management practices such as silt fence, straw bales, check dams, sediment basins and other methods to capture potential sediment from exposed soils. In addition, the amount of clearing of existing vegetation would be minimized to the greatest extent possible and areas of exposed soils would be stabilized as soon as possible to prevent additional erosion. Following construction, the generated runoff would be treated in accordance with the state guidelines for stormwater management and then released to surface waters. Any crossing draining to a reservoir may include stormwater management plans designed specifically to address any potential impact to the surface water supply.

Groundwater

The Build Alternatives would be constructed on the surface, with no anticipated deep excavations, and are anticipated to have no or minor affects to groundwater in the aquifers along the corridor. Only small changes in the movements of the shallow groundwater table are likely to occur during grading and construction. In addition, the urbanized nature of the sections of the corridor with the greatest construction footprint make it unlikely that runoff from the post-construction interstate would reach the groundwater table. The generated runoff would be treated in accordance with the state guidelines for stormwater management and then released to surface waters.

The construction footprints of each Build Alternative would not impact the identified public groundwater supply well located north of the west bound exit ramp at Exit 211 (Talleysville) in New Kent County. It is possible that there are private drinking water wells within the vicinity of the study area. No determination was made for this study which properties utilize public water and those which utilize well water. Further investigations during the right of way acquisition would be necessary to make these determinations. However, potential impacts to any groundwater well resulting from any of the Build Alternatives are likely non-existent.

As noted by the VDH, potential impacts to public water distribution systems or sanitary sewage collection systems must be verified by the local utility prior to construction practices. Further investigations to determine the presence, operational status, and location of individual wells would be performed as part of property acquisition and right of way management for the construction project. Closures and/or relocation of the identified New Kent Farms public well (or any other identified well), if required, would be completed by following the Virginia Waterworks Regulation and other applicable VDOT or locality standard. Closures and relocation of private wells, if required, would be completed by using the Virginia Private Well Regulation and other applicable VDOT standard or locality standard.

Runoff generated both during and post-construction would not likely reach the groundwater table. In addition, the generated runoff would be treated in accordance with the state guidelines for stormwater management and then released to surface waters.

G. Chesapeake Bay Resource Protection Areas *Methodology and Existing Conditions*

The study area corridor is located within the Chesapeake Bay Watershed. As part of their commitment to protecting the Bay, localities have adopted the Chesapeake Bay Preservation Act (The Bay Act) into its local ordinance in 1990. The Bay Act offers guidelines and requirements to protect and improve the water that flows into the Chesapeake Bay. The vegetated riparian buffers located along the streams and wetlands are included as RPAs under the Bay Act. RPAs include the land area within 100 feet of a perennial stream bank or edge of wetlands adjacent to the perennial stream. RPAs are protected under both state law and local ordinances. In general, no development, land disturbance, or vegetation removal is allowed in an RPA without approval by the state and County. The Bay Act also designates Resource Management Areas (RMAs). RMAs include floodplains, highly erodible soils (including steep slopes), highly permeable soils, non-tidal wetlands not included in RPAs, and any other sensitive lands that either County feels are necessary to help protect the quality of water resources. Development is permitted within RMAs, but it must adhere to the criteria established in the county's comprehensive plan.

Potential Impacts and Mitigation Measures

According to the Division of Chesapeake Bay Local Assistance the construction, installation, operation, and maintenance of roadways and their appurtenant structures are conditionally exempt from the *Chesapeake Bay Preservation Area Designation and Management Regulations*, provided they are constructed in accordance with:

- Regulations promulgated pursuant to the Erosion and Sediment Control Law (§ 10.1-560 et. seq. of the Code of Virginia) and the Stormwater Management Act (§ 10.1-603.1 et. seq. of the Code of Virginia).
- An erosion and sediment control plan and a stormwater management plan approved by the VDCR, or local water quality protection criteria at least as stringent as the above state requirements.

Any improvement work associated with the project has the potential to affect RPA and RMA regions. Due to the regulation exemption stated above, the project is not under jurisdiction in terms of The Bay

Act. Therefore, provided that the guidance in the above section is followed, no additional avoidance or minimization techniques are necessary.

H. Floodplains

Methodology and Existing Conditions

Steep slopes typically separate the uplands from the bottom land along the region's streams. Narrow floodplains line the upper reaches of streams throughout most of the study area. Broader floodplains occur along the Chickahominy River, Boar Swamp, Rumley Marsh, Diascund Creek, Beaverdam Creek, Wahrani Swamp, Queen Creek, and Newmarket Creek. Dams have inundated the floodplains along Shiminoe Creek and the Warwick River in the study area.

Several federal regulations govern fill and construction in floodplains to ensure that proper consideration is given to the avoidance and mitigation of adverse floodplain effects. These regulations include Executive Order 11988, US Department of Transportation Order 5650.2, entitled the "Floodplain Management and Protection", and the National Flood Insurance Act of 1968. In Virginia, the VDCR is responsible for coordination of all state floodplain programs, and floodplains are also governed by local Flood Insurance Programs administered by localities and supervised by the Federal Emergency Management Agency (FEMA). The VDCR Floodplain Management Program and VDOT construction specifications for the roadway itself also address downstream floodplain and floodway effects.

The approximate locations of 100-year floodplain limits in the corridor are based on data from FEMA. The 100-year floodplain refers to the areas along or adjacent to a stream or body of water that are capable of storing or conveying floodwaters during a 100-year storm. The approximate locations of the 100-year floodplains in the corridor are shown on the mapping in **Appendix I.**

Within the study area boundary, FEMA designated 100-year floodplains are located alongGillies Creek and an unnamed tributary, Boar Swamp and an unnamed tributary, the Chickahominy River and an unnamed tributary, Higgins Swamp, Crump Swamp, Allens Run, Toe Ink Swamp and an unnamed tributary, Schiminoe Creek, Rumley Marsh, Diascund Creek and two unnamed tributaries, Beaverdam Creek, Wahrani Swamp, upper limits of Diascund Creek Reservoir, Barnes Swamp, Skimino Creek, Whiteman Swamp and an unnamed tributary, and Blows Mill Run. The total acreage of mapped 100-year floodplains within the study area corridor is 50.01 acres. The total acreage of floodplain for each stream channel is summarized in **Table 20.** Individual floodplain acreages within the corridor ranged from 0.12 acres (Barnes Swamp) to 14.96 acres (Chickahominy River). In addition to the Chickahominy River, Rumley Marsh and the upper limits of the Diascund Creek Reservoir each had five or greater acres of designated floodplain within the study area.

Potential Impacts and Mitigation Measures

No-Build Alternative

The No-Build Alternative would not involve any project-related construction or changes to the natural environment. As a result, project-related environmental effects from the No-Build Alternative are not anticipated.

Build Alternatives

The majority of the floodplain encroachments from the proposed Build Alternatives would be from the perpendicular crossing of floodplains, not from longitudinal (parallel) encroachments which were avoided. These longitudinal crossings have been avoided because they would result in more floodplain fill, reducing conveyance and floodplain storage.

Table 20: FEMA 100-year Floodplains Located within the Study Area

Stream Name	Map No.	Acreage in Study Area
Unnamed tributary to Gillies Creek	4	0.95
Gillies Creek	4	3.76
Boar Swamp	8	0.67
Unnamed tributary to Boar Swamp	8	0.56
Chickahominy River	9	14.96
Higgins Swamp	9	2.79
Unnamed Tributary to the Chickahominy River	10	0.21
Crump Swamp	11	0.55
Unnamed Tributary to Toe Ink Swamp	11	1.42
Allens Run	12	0.36
Toe Ink Swamp	12	1.10
Schiminoe Creek	13	0.84
Rumley Marsh	14	5.00
Diascund Creek	15	1.71
Unnamed Tributary to Diascund Creek	16	0.64
Unnamed Tributary to Diascund Creek	16	0.38
Beaverdam Creek	19	4.77
Wahrani Swamp	19	0.69
Upper Limits of Diascund Creek Reservoir	20	5.55
Barnes Swamp	20	0.12
Skimino Creek	25	0.18
Whiteman Swamp	30	1.01
King Creek	31	1.05
Blows Mill Run	33	0.76
	Grand Total	50.01

Tables 21 and 22 summarize the potential specific encroachments (expressed as area in acres crossed by the construction footprint) into FEMA-designated 100-year floodplains for each Build Alternative and for each floodplain system. The approximate locations of the 100-year floodplain crossing for each Build Alternative are shown on the mapping in **Appendix I.** All of the Build Alternatives would affect each identified 100-year non-tidal floodplain to some degree. Cumulatively, the impacts would be least with Alternatives 1B/2B and greatest with Alternatives 1A/2A. Placement of a substantial amount of fill is not anticipated in any of the floodplains. It is expected that the majority of encroachments would result from minimal cut/fill activities and the construction of bridges crossing the systems.

Table 21: Potential Impacts to FEMA 100-year Floodplains

Build Alternative	Potential Encroachment (acres)
Alternatives 1A/2A	21.08
Alternatives 1B/2B	17.56
Alternative 3	20.80

Table 22: Potential Impacts to FEMA 100-year Floodplains for Individual Stream Systems

Table 22: Potential impacts to FEMA 100-year Floodplains for Individual Stream Systems					
Stream Name	Map No.	Acreage Impacted by Alternatives 1A/2A	Acreage Impacted by Alternatives 1B/2B	Acreage Impacted by Alternative 3	
Unnamed tributary to Gillies Creek	4	0.82	0.82	0.82	
Gillies Creek	4	2.47	1.95	2.42	
Boar Swamp	8	0.49	0.39	0.45	
Unnamed tributary to Boar Swamp	8	0.46	0.34	0.46	
Chickahominy River	9	10.81	8.26	9.68	
Higgins Swamp	9	0.87	0.00	0.41	
Unnamed Tributary to the Chickahominy River	10	0.00	0.00	0.00	
Crump Swamp	11	0.17	0.19	0.22	
Unnamed Tributary to Toe Ink Swamp	11	0.18	0.20	0.28	
Allens Run	12	0.12	0.12	0.15	
Toe Ink Swamp	12	0.74	0.72	0.74	
Schiminoe Creek	13	0.14	0.15	0.19	
Rumley Marsh	14	0.17	0.32	0.45	
Diascund Creek	15	0.24	0.34	0.37	
Unnamed Tributary to Diascund Creek	16	0.15	0.18	0.20	
Unnamed Tributary to Diascund Creek	16	0.24	0.15	0.16	
Beaverdam Creek	19	0.55	0.62	0.84	
Wahrani Swamp	19	0.07	0.12	0.14	
Upper Limits of Diascund Creek Reservoir	20	0.31	0.62	0.74	
Barnes Swamp	20	0.00	0.00	0.00	
Skimino Creek	25	0.03	0.03	0.02	
Whiteman Swamp	30	1.01	1.01	1.01	
King Creek	31	1.05	1.05	1.05	
Blows Mill Run	33	0.00	0.00	0.00	
Gran	d Totals	21.08	17.56	20.80	

The potential acres of floodplain impacts for each Build Alternative are tentative estimates, as the engineered cut/fill calculations are preliminary and may be subject to change. In addition, the estimates are based on the footprint of the area, and not necessarily a direct crossing or impact to the floodplain. Many of these "crossings" would actually consist of the widening of existing bridges, thus reducing the actual impact acreage.

Individual impacts to any one floodplain would be relatively small in both size and severity. Future design would focus on avoiding and minimizing floodplain encroachment to ensure that the design is consistent with Executive 11998 and FHWA policy as set forth in 23 CFR 650. Hydraulic and hydrologic studies would be performed to determine if any floodplain encroachments would have negative effects on storage areas for floodwaters or alter flooding characteristics. Techniques that would be investigated to further minimize or avoid impacts may include alignment shift to ensure the narrowest possible crossing and bridging of floodwaters to further reduce encroachment and allow for unrestricted passage of floodwaters. At proposed bridge crossings, the minimum number of piers to ensure structural stability should be placed within floodways. Feasible construction methods that would not require the placement of construction causeways would be evaluated during the design phase. Should it become necessary, fill

placed for temporary construction causeways or work bridges would be removed and preconstruction floodplain conditions would be restored immediately following construction. Breastwalls and fill placed within floodplains for bridge abutments would be minimized.

All construction occurring within the FEMA designated 100-year floodplain must comply with the VDOT floodplain construction requirements which does not allow any change to the surface water elevation. These requirements consider structural evaluations, fill levels, and grading elevations. In accordance with the VDOT requirements, no change in surface water elevation would be permissible as part of the project final design and construction. Avoidance and minimization efforts, including the bridging/spanning of these systems, would be followed to the greatest extent practicable. In addition to mitigation measures designed to reduce the amount of floodplain encroachment by Alternatives, VDOT's highway construction specifications require implementation of stormwater management practices to address concerns such as post-development runoff associated with storm events and downstream channel capacity. These standards require that stormwater management facilities be designed to reduce stormwater flows to pre-construction conditions for up to a 10-year storm event. Also, during final design, a hydraulic study would be conducted that would ensure that no substantial increase in downstream flooding would occur.

Also, indirect impacts may include increased sedimentation entering the systems from disturbed floodplains as a result of the construction activities. To minimize indirect impacts to the floodplain, the appropriate erosion and sediment control measures, in accordance with VDCR standards, should be implemented and maintained. Hydrology and hydraulic analyses may be necessary to determine if there would be a rise in normal water surface elevation at the areas of potential encroachment, in which case FEMA may require a revision to the FIRMs during final design.

I. Wild and Scenic Rivers

Methodology and Existing Conditions

The Wild and Scenic Rivers Act of 1968 is a federal act adopted for specific free-flowing rivers that have outstanding natural, cultural, or recreational features. The Act classifies designated rivers as Wild, Scenic, or Recreational. Wild river areas are those rivers or sections of rivers that are free of impoundments and generally inaccessible except by trail, with watersheds or shorelines essentially primitive and waters unpolluted. These represent areas of primitive America. Scenic river areas are those rivers or sections of rivers that are free of impoundments, with shorelines or watersheds still largely primitive and shorelines largely undeveloped, but still accessible in places by roads. Recreational river areas are those rivers or sections of rivers that are readily accessible by road or railroad, that may have some development along their shorelines, and that may have undergone some impoundment or diversion in the past.

All rivers classified under the Act must first be listed on the National Rivers Inventory (NRI). The NRI is a federal list that includes rivers that are free-flowing and have one or more "outstandingly remarkable values." Under provisions of the Act, if a federal action compromises the designation of a Wild and Scenic River or forecloses the possibility of future designation (of a NRI river) under the Act, implementation of the federal action must be coordinated with the U.S. Department of Interior. According to the USFWS Wild and Scenic Rivers list (2011), there are no Wild, Scenic, or Recreational Rivers designated under the federal Act that exist within the study area. There are also no rivers within the study area listed in the NRI.

The Virginia Scenic Rivers Program's (established under the Commonwealth of Virginia Scenic Rivers Act) intent is to identify, designate, and help protect rivers and streams that possess outstanding scenic, recreational, historic, and natural characteristics of Statewide significance for future generations. The Commonwealth of Virginia Scenic Rivers Act affords protection to waters of Statewide importance. The

VDCR oversees the Commonwealth's Scenic Rivers Program. Based on comments received from VDCR, there are no systems within the study area corridor listed as a Scenic River. While the section of the Chickahominy River from Route 360 to the New Kent County line is listed as a Scenic River, the section of the Chickahominy River crossing the study area corridor was identified as a potential Scenic River.

Potential Impacts and Mitigation Measures

Since there are no federally designated systems in the study area, the proposed project poses no direct or indirect impacts to Wild, Scenic, or Recreational rivers and no avoidance or minimization techniques are necessary.

There are no state listed Scenic Rivers within the study area corridor. The VDCR commented that the Chickahominy River is a potential Scenic River. The No-Build Alternative would have no impact to the Chickahominy River. VDCR recommended that any impacts to the river crossing by the Build Alternatives be mitigated using native plants to stabilize land disturbance in the study area. In addition, the existing crossing consists of a span bridge, which would likely be widened as part of the improvements associated with all of the Build Alternatives, thereby, reducing any potential effects on the system.

J. Threatened, and Endangered Species

Methodology and Existing Conditions

The USFWS and the National Marine Fisheries Service (NMFS) regulate and protect federally listed threatened and endangered species under the Endangered Species Act (ESA) of 1973 with the primary goal of conserving and recovering listed species. The ESA, with few exceptions, prohibits activities affecting threatened and endangered species unless authorized by a permit. The legal federal status of a species is determined by the USFWS and the NMFS. This status is used for all animals listed as endangered or threatened by the United States government and receiving protection under the federal ESA. Listed federally endangered (FE) species are those taxon threatened with extinction throughout all or a substantial portion of its range. Listed federally threatened (FT) species are taxon likely to become endangered in the foreseeable future.

In addition to the federal oversight, threatened and endangered species are also regulated at the state level. The Virginia Department of Game and Inland Fisheries (VDGIF) has adopted the federal list as well as a state list of endangered and threatened species, with the primary focus of managing Virginia's wildlife to maintain optimum populations of all species and conserve biodiversity. In addition, through a Memorandum of Agreement established between the VDCR and Virginia Department of Agriculture and Consumer Services (VDACS), the VDCR represents VDACS in comments regarding potential impacts on state-listed threatened and endangered plants and insect species. The legal state status is determined by the VDGIF (all animals except insects) and the VDACS (plants and insects). A state endangered (SE) species is defined as a species that is in danger of extinction throughout all or a substantial portion of its range. A state threatened (ST) species is defined as a species that is likely to become endangered within the foreseeable future.

As part of the project scoping process, comments were requested from the USFWS and NMFS to determine the presence of federal threatened or endangered species and with the VDGIF, VDCR, and VDACS for the identification of state threatened and endangered species. Comments from the agencies and additional information related to threatened and endangered species are included in **Appendix J**. No comments have been received from the USFWS, NMFS, or VDGIF. However, as detailed below, various database searches and reviews have been conducted for both threatened and endangered species.

The study identified ten federal and state threatened and/or endangered species or their habitat located within a two mile radius of the study area corridor. Most of these species were listed with numerous occurrences throughout the corridor. These species are listed in **Table 23**, and the mapping in **Appendix K** shows the location of these resources along the corridor. This summary only includes species which have been documented/confirmed through the review process within the two mile radius of the center line of the study area, in addition to the assessed potential habitat areas for small whorled pogonia conducted as part of the I-64 Study.

The information generated from the resources listed below, in addition to other natural resource agency documents and information, was used to develop a Species Conclusion Table for the identified species. This information is included in **Appendix J**.

The following sections provide additional details regarding the resource reviews, agency coordination, and identified species.

1. VDCR Comments

The VDCR-DNH commented that, according to its search in the agency's Biotic Data System, numerous natural heritage resources have been documented within two miles of the study area corridor. Natural heritage resources are defined by the agency as the habitat or rare, threatened, or endangered plant and animal species, unique or exemplary natural communities, and significant geologic formations. The table generated by the agency is included in **Appendix J**. VDCR-DNH specifically noted the potential for the following two plants to occur in the study area: Small whorled pogonia (*Isotria medeoloides*) which is currently classified as threatened by the USFWS and as endangered by the VDACS, and Swamp pink (*Helonias bullata*), which is currently classified as threatened by the USFWS and as endangered by the VDACS. Through the scoping letter response, VDCR noted that, within a two mile radius of the corridor, Small whorled pogonia was noted in three instances, with one of those occurrences at Ware Creek, and Swamp pink was noted in one instance at Broadwater Creek.

Table 23: Threatened and Endangered Species Mapped within a Two Mile Radius of the Study Area

Common Name	Scientific Name	Legal Status
Rafinesque's eastern big-eared bat	Corynorhinus rafinesquii macrotis	SE
Peregrine falcon	Falco peregrinus	ST
Canebrake rattlesnake	Crotalus horridus	SE
Mabee's salamander	Ambystoma mabeei	ST
Eastern tiger salamander	Ambystoma tigrinum tigrinum	SE
Loggerhead sea turtle	Caretta caretta	FT / ST
Bald eagle	Haliaeetus leucocephalus	ST
Small whorled pogonia	Isotria medeoloides	FT / SE
Swamp pink	Helonias bullata	FT / SE
Harper's fimbristylis	Fimbristylis perpusilla	SE

A summary of the listed plant and animals provided by VDCR is included in **Table 24**. This table lists the common and scientific names, the federal and state listing status, the number of occurrences identified within a two mile radius of the corridor, and the Global and state ranks of each species.

Table 24: VDCR Listed Threatened and Endangered Species within a Two Mile Radius of the Study Area

Common Name	Scientific Name	Global Rank	State Rank	Legal Status	Number of Occurrences
Bald eagle	Haliaeetus leucocephalus	G5	S2S3B, S3N	ST	7
Canebrake rattlesnake	Crotalus horridus (Coastal Plain population)	G4	S 1	SE	5
Mabee's salamander	Ambystoma mabeei	G4	S1S2	ST	5
Eastern tiger salamander	Ambystoma tigrinum	G5	S 1	SE	1
Harper's fimbristylis	Fimbristylis perpusilla	G2	S 1	SE	1
Small whorled pogonia	Isotria medeoloides	G2	S2	FT/SE	3
Swamp Pink	Helonias bullata	G3	S2S3	FT/SE	1
Peregrine falcon	Falco peregrinus	G4	S1B, S2N	ST	1

Global ranks are assigned by a consensus of the network of natural heritage programs, scientific experts, and NatureServe (a non-profit conservation organization) to designate the range wide rarity of a species or subspecies. The ranks are assigned after considering a suite of factors including the number of occurrences (populations), number of individuals, and severity of threats to the species and its habitats. Global ranks found in the Rare Plant and Animal Lists identified for the I-64 Study are as follows:

- **G2** Very rare and imperiled with 6 to 20 occurrences or few remaining individuals; or because of some factor(s) making it vulnerable to extinction.
- **G3** Either very rare and local throughout its range or found locally (even abundantly at some of its locations) in a restricted range; or vulnerable to extinction because of other factors. Usually fewer than 100 occurrences are documented.
- **G4 -** Common and apparently secure globally, although it may be rare in parts of its range, especially at the periphery.
- **G5** Very common and demonstrably secure globally, although it may be rare in parts of its range, especially at the periphery.

State ranks are assigned in a similar manner to global ranks, with values that range from S1-S5, but consider only factors within the political boundaries of Virginia. State ranks found in the Rare Plant and Animal Lists within a two mile radius of the I-64 study area are as follows:

- **S1** Extremely rare and critically imperiled with 5 or fewer occurrences or very few remaining individuals in Virginia; or because of some factor(s) making it especially vulnerable to extirpation in Virginia.
- **S2** Very rare and imperiled with 6 to 20 occurrences or few remaining individuals in Virginia; or because of some factor(s) making it vulnerable to extirpation in Virginia.

- **S3** Rare to uncommon in Virginia with between 20 and 100 occurrences; may have fewer occurrences if found to be common or abundant at some of these locations; may be somewhat vulnerable to extirpation in Virginia.
- **S_B** Breeding status of an animal (primarily used for birds) in Virginia; these species typically inhabit Virginia only during the breeding season.
- S_B/S_N Breeding and nonbreeding status of an animal (primarily used for birds) in Virginia

2. VDACS Comments

In response to the project scoping request, VDACS commented that although "unlikely", there is the possibility that endangered plants or insects could occur in the vicinity of the I-64 corridor. The agency noted that while these species were found in the localities along the study area, it is not known if they are located within the study area boundary. The species with the greatest potential for occurring along the study area corridor include Small whorled pogonia, Swamp pink, and New Jersey rush (*Juncus caesariensis*).

3. USFWS Information, Planning, and Conservation On-Line System

While no official comments were received from the USFWS to date, McCormick Taylor conducted the USFWS Information, Planning, and Conservation (IPaC) on-line system for the study area corridor. Through the use of the USFWS IPaC on-line system, several federal threatened or endangered species were identified within the study area boundary. These species included Small whorled pogonia (*Isotria medeoloides*), classified as threatened in 1994 and occurring in Henrico, New Kent, James City and York Counties; Swamp pink (*Helonias bullata*), classified as threatened in 1988 and occurring in the City of Richmond and Henrico and New Kent Counties; Piping plover (*Charadrius melodus*), classified as threatened in 1986 and occurring in the City of Hampton, and Sensitive joint-vetch (*Aeschynomene virginica*), classified as threatened in 1992 and occurring in York County. However, the exact locations of these occurrences were not identified. The IPaC species list and information is included in **Appendix J.**

4. Center for Conservation Biology Bald Eagle Nest Locator

Both the VDGIF and the VDCR recommends contacting the Center for Conservation Biology (CCB) at the College of William and Mary to obtain the updated information regarding Bald eagle (*Haliaeetus leucocephalus*) issues. Additionally, McCormick Taylor conducted a Bald eagle nest locator search using the CCB on-line system. Bald eagles are currently de-listed under the federal ESA; however, they are still recognized as a threatened species at the state level and are protected by the federal Bald and Golden Eagle Protection Act (Eagle Act) (16 U.S.C. §668-668d) and the Migratory Bird Treaty Act (MBT Act) (16 U.S.C. §703-712).

The CCB's nest locator was used to determine the approximate location of eagle's nests throughout the study area corridor. A total of eleven nests were found to be within a two mile radius of the study area. However, no nests were located within 660 feet of the study area corridor, with the closest nest (Nest Code NK0702 south of the mainline near mile marker 222 in New Kent County) located approximately 1,450 feet from the study area boundary. Nests located within the 660 foot radius considered the nest protection zone, would elevate the review and protective measures required by the agencies. A summary of the CCB's nest location results are included in the table below and included on the mapping in **Appendix K**.

Table 25:	CCB Bald I	Eagle Nest Loc	ations within a	a Two Mile R	Radius of the Study Area

County	Nest Code	Status
New Kent	NK0701	Active / Occupied
New Kent	NK0702	Active / Occupied
James City	JC0704	Active / Occupied
James City	JC0805	Active / Occupied
James City	JC1107	Active / Occupied
James City	JC0401	Active / Occupied
James City	JC0703	Active / Occupied
James City	JC1108	Recently Active
York	YK1103	Active / Occupied
York	YK0204	Active / Occupied
York	YK0703	Active / Occupied

Bald eagle concentrations areas are also located along the James River and the river's tributaries in the vicinity of the project corridor.

5. VDGIF Virginia Fish and Wildlife Information Service Database

In addition to requesting threatened and endangered species information as detailed above, the federal and state threatened and endangered species were also mapped using the Virginia Fish and Wildlife Information Service (VFWIS) database maintained by VDGIF.

The location of listed state and federal threatened and endangered species (animal only) identified within a two mile radius of the corridor generated from the VFWIS is included on the mapping in **Appendix K** and summarized in **Table 26**. This summary only includes species which have been documented/confirmed within the two mile radius of the center line of the study area corridor.

Table 26: VFWIS Database Documented Threatened and Endangered Species within a Two Mile Radius of the Study Area

Common Name	Scientific Name	Legal Status	TIER	Feature Count
Rafinesque's eastern big-eared bat	Corynorhinus rafinesquii macrotis	SE	I	1
Peregrine falcon	Falco peregrinus	ST	I	3
Canebrake rattlesnake	Crotalus horridus	SE	II	30
Mabee's salamander	Ambystoma mabeei	ST	II	55
Eastern tiger salamander	Ambystoma tigrinum tigrinum	SE	II	1
Loggerhead sea turtle	Caretta caretta	FTSE	I	4

Through analysis of the VDGIF VFWIS data, six species were identified as either state or federally threatened or endangered. Three species are considered Tier I and three species are considered Tier II. As indicated in the VDGIF Virginia's Comprehensive Wildlife Conservation Strategy Plan (2005), Tier 1 and Tier II species are defined as the following:

Tier I - Critical conservation need. Faces an extremely high risk of extinction or extirpation. Populations of these species are at critically low levels, face immediate threat(s), or occur within an extremely limited range. Intense and immediate management action is needed.

Tier II - Very high conservation need. Has a high risk of extinction or extirpation. Populations of these species are at very low levels, face real threat(s), or occur within a very limited distribution. Immediate management is needed for stabilization and recovery.

Bald eagles (which are listed as a Tier II species) are not included in this section, but are discussed in Section J.4.

As shown on the mapping in **Appendix K**, of the species identified, the Mabee's salamander (near Exit 243 - Busch Gardens and Exit 250 - Fort Eustis, and Mile Marker 261) and the Canebrake rattlesnake (near Exit 256 - Victory Boulevard and from Exits 258 - J Clyde Morris Boulevard to 261 - Hampton Roads Center Parkway) are located in the immediate vicinity of the study area corridor.

6. Species Profiles

The following provides general summaries of the major state or federal threatened or endangered species documented by the agencies (either through database searches or written correspondence) within a two mile radius of the centerline of the study area corridor. The general location of the documented species is included on the mapping in $\bf Appendix~\bf K$.

Small whorled pogonia (Isotria medeoloides) - Federal Threatened/State Endangered

The small whorled pogonia was listed as FE for protection under the Endangered Species Act on September 9, 1982 and was reclassified from endangered to threatened on October 6, 1994 (USFWS 1982, 1994). The Small whorled pogonia is listed as state-endangered by the Commonwealth of Virginia. In Virginia, most populations occur in the coastal plain and piedmont. Small whorled pogonia has been documented in 21 counties (and one city), including James City County, New Kent County, York County, and the City of Williamsburg (USFWS 2012). Through their response as part of the scoping process, VDCR indicated that small whorled pogonia was noted in three instances within a two mile radius of the study area corridor, with one of those indicated at Ware Creek.

Small whorled pogonia typically occurs on mesic sites in mixed-deciduous or mixed-deciduous coniferous forests that are generally in second- or third-growth successional stages. Most occupied sites have been cutover in the past and allowed to regenerate for at least several decades. Occupied sites typically have sparse to moderate ground cover, a relatively open understory, and proximity to long persisting canopy breaks associated with logging roads, streams, and large tree falls. Direct destruction, as well as habitat loss and alteration are principle reasons for the species' decline.

As part of this study, EEE Consulting, Inc. conducted a reconnaissance level habitat evaluation for the FT, SE Small whorled pogonia within the study area corridor. Potential habitat was identified using a combination of desktop review of relevant data resources, windshield reconnaissance conducted from a vehicle, and pedestrian spot checks of the highest quality habitat areas. Of the fifteen areas identified as the potential highest quality habitat areas, only the southeast area of Exit 238 (Colonial Williamsburg) was determined to be of high potential habitat. The other fourteen areas were either determined to be of medium (13 areas) or low (1 area) quality. The full report and mapping showing the location of the field assessed areas and their classifications are included in **Appendix L**.

Swamp pink (Helonias bullata) – Federal Threatened/State Endangered

Swamp pink inhabits groundwater-influenced, perennially saturated, nutrient-poor headwater wetlands and is sensitive to hydrologic alterations to its habitat. The plant is commonly associated with some evergreens, including Pitch pine, Atlantic white cedar, American larch, Black spruce, Red spruce, and with Red maple. It often grows on hummocks formed by trees, shrubs, and sphagnum moss. The hummocks keep the roots moist but not submerged. Through their response as part of the scoping

process, VDCR indicated that within a two mile radius of the corridor, Swamp pink was noted in one instance at Broadwater Creek.

The major direct threat to this species is habitat loss. Indirect threats result from activities that affect the hydrologic regime including such upslope activities as timber harvesting, land clearing and development, and agriculture. Downstream threats to the hydrology of a swamp pink habitat arise from flooding caused by road crossings with culverts that become blocked and beaver activity.

Piping plover (Charadrius melodus) - Federal Threatened/State Threatened

The Piping plover was listed as federal threatened in Virginia in 1986 and is currently listed as state threatened in Virginia. The Piping plover is a small, inconspicuous shorebird with a sand-colored back, narrow black neck ring, white belly, orange legs and a small orange and black bill.

This species is considered native to Virginia. Piping plover is known to occur in Accomack, the City of Hampton, Northampton, City of Portsmouth, and City of Virginia Beach. Virginia is part of this population's southern breeding range and since 1986 has supported a relatively stable number of nesting pairs. The Piping plover lives the majority of its life on open sandy beaches or rocky shores, often in high, dry sections away from water. Piping plovers typically nest on sparsely vegetated ocean-facing beaches, sand flats and washovers. Since the late 1990's, 100% of the breeding activity in Virginia has occurred on the Eastern Shore's barrier islands. Piping plovers have many natural enemies such as raccoons, foxes, crows, gulls and other birds and mammals. Storms and spring high tides often wash out a portion of the nests and/or drown flightless chicks. In addition, the prevalence of pets and increased pedestrian and off-road vehicle traffic on nesting beaches reduce the success of nesting pairs.

Piping plover was identified as potentially occurring within the vicinity of the study area through the IPaC database. While the Piping plover is considered state threatened, the VDGIF VFWIS data did not indicate the presence of the bird within a two mile radius of the corridor.

Sensitive joint-vetch (Aeschynomene virginica) – Federal Threatened/State Endangered

Sensitive joint-vetch is an annual legume native to the eastern United States. In Virginia, populations are found along the Potomac, Mattaponi, Pamunkey, Rappahannock, Chickahominy, and James Rivers and their tributaries. This plant usually attains a height of three to six feet in a single growing season, but may grow as tall as eight feet. The flowers are yellow, streaked with red and the fruit is a pod, turning dark brown when ripe. The species is known to occur in Charles City, Chesterfield, Essex, Henrico, James City, King and Queen, King William, New Kent, Richmond, Stafford, Surry, and Westmoreland Counties, primarily along the Potomac, Rappahanock, Mattaponi, Pamunkey, Chickahominy, and James Rivers. It is currently listed as a FE and SE species.

Sensitive joint-vetch occurs in fresh to slightly brackish tidal river systems, within the intertidal zone where populations are flooded twice daily. It typically occurs at the outer fringe of marshes or shores; its presence in marsh interiors may be a result of nutrient deficiencies, ice scouring, or muskrat herbivory. The Sensitive joint-vetch is found in locations where plant diversity is high and annual species are prevalent. Bare to sparsely vegetated substrates appear to be a habitat feature of critical importance for establishment and growth of this species. Plants flower from July through September and into October in some years. Fruits are produced from July through late October, concurrent with flowering. Direct impact and habitat destruction are some of the highest threats to this species.

Sensitive joint-vetch was identified as potentially occurring within the vicinity of the study area through the IPaC database. While the plant is considered SE, it was not identified within a two mile radius of the study area corridor through the state agency information review and coordination efforts.

Bald eagle (Haliaeetus leucocephalus) – State Threatened

Bald eagles are currently de-listed under the federal ESA; however, they are still recognized as a threatened species at the state level and are protected by the federal Bald and Golden Eagle Protection Act (Eagle Act) (16 U.S.C. §668-668d) and the Migratory Bird Treaty Act (MBT Act) (16 U.S.C. §703-712). A large raptor, the Bald eagle has a wingspread of about 7 feet. Adults have a dark brown body and wings, white head and tail, and a yellow beak. Juveniles are mostly brown with white mottling on the body, tail, and undersides of wings. Adult plumage usually is obtained by the 6th year. In flight, the Bald eagle often soars or glides with the wings held at a right angle to the body.

The Bald eagle is not overly common to the Coastal Plain and Piedmont regions, remaining relatively close to large bodies of water. However, they are more common in summer and winter in the Chesapeake Bay region and surrounding counties. The Bald eagle prefers habitats near seacoasts, rivers, large lakes, oceans, and other large bodies of open water with an abundance of fish. The Bald eagle requires old-growth and mature stands of coniferous or hardwood trees for perching, roosting, and nesting. Selected trees must have good visibility, an open structure, and proximity to prey, but the height or species of tree is not as important as an abundance of comparatively large trees surrounding the body of water. Forests used for nesting should have a canopy cover of no more than 60%, and no less than 20%, and be in close proximity to water.

While the Bald eagle may be sensitive to human activity, it has been known to quickly adjust to constant noise associated with transportation activity. Since the banning of pesticides, the species has made extensive recovery across the United States. The current primary threat to the species is habitat fragmentation and destruction.

Rafinesque's eastern big-eared bat (*Corynorhinus rafinesquii macrotis*) – State Endangered The Rafinesque's eastern big-eared bat was designated as a SE species in 1987 and listed as a federal candidate in 1994. This is a medium sized bat, with the dorsal hair gray-brown with black bases, and the ventral hair whitish-yellowish with black bases. The fur is long and shaggy and it has huge ears up to twice the length of the head connected across the forehead. There is a glandular mass on either side of the

muzzle, and elongated nostril openings. The total length (male smaller than female) is 80-110 mm, with a wingspread from 265-301 mm, and a weight of 7.9-13.6 grams.

The bat is incidental in Virginia because it has adapted to temperate, arboreal zones found only in the extreme southeast. This bat is rare in Virginia and particularly susceptible to human disturbance. Both subspecies are at the edge of their ranges in Virginia, so their occurrence here is tenuous at best. They are uncommon to rare throughout their range, and both seem to be declining. They prefer roosting sites near mature forests and adjacent to rivers and other permanent bodies of water; manmade structures that are most often used have few openings to the attic and have tin roofs, type of structures may have been influence by the socio-economics of the area (eg. types of houses built); they prefer structures with low light levels. The attics of structures were used more due to higher temperatures during gestation and early growth periods. More closed canopy forest surround occupied sites than the unoccupied ones; tree cavities or other alternate roosts are important to avoid predators and fulfill thermoregulatory needs; tree roosts may be better winter roosts.

Peregrine falcon (Falco peregrinus) - State Threatened

Due to recovery success, the Peregrine falcon has been federally delisted; however, the bird is still listed as ST. Through the scoping process, VDCR indicated that the bird was noted within a two mile radius of the study area corridor.

The Peregrine falcon is characterized by long pointed wings having a distinct sickle-shaped silhouette. Also unique to this species is the notched beak that is used to kill prey by severing the spinal column at

the neck. The falcon is a crow-sized bird, weighing just over two pounds with a wing span of approximately 3 feet. An adult peregrine has a dark grey back and crown, dark bars or streaks on a pale chest and abdomen, and heavy malar (cheek) stripes on the side of the face. Immature peregrines are buff colored in front and have dark brown backs; adults are white or buff in front and bluish-gray on their backs. Females and males are identical appearance; however, the female can be a third larger than the male. They typically nest on the side of cliffs, or if in cities, on the roofs of large buildings.

Canebrake rattlesnake (Crotalus horridus) – State Endangered

The Canebrake rattlesnake is a large venomous snake reaching a maximum length in Virginia of about 5.5 feet. As the only rattlesnake found in southeastern Virginia, it is easily identified by its distinctive black tail and rattle. The Canebrake is a physically distinct variant of the timber rattlesnake (*Crotalus horridus*) which ranges from New England to Minnesota and south to Florida and Texas. In Virginia, Canebrakes occur only as two populations in the southeastern corner of the state. On the Lower Peninsula they occur in the Cities of Hampton and Newport News, and York County; and south of the James River they are still found in Isle of Wight County, and in the Cities of Suffolk, Chesapeake, and Virginia Beach.

Mature hardwood forests are the preferred habitat of Canebrake rattlesnakes, but the snakes also are found in mixed hardwood-pine forests, cane thickets, and in the ridges and glades of swamps. They prefer areas with numerous logs and a substantial layer of leaves and humus. Canebrakes overwinter in the bases of hollow trees and stumps and in the underground tunnels resulting from stump and root decomposition. Habitat destruction or modification, and persecution by humans, are the primary threats to canebrake rattlesnakes.

Through the scoping process, VDCR indicated that the Canebrake rattlesnake (Coastal Plain population) was noted in five instances within a two mile radius of the study area corridor.

Mabee's salamander (Ambystoma mabee) - State Threatened

The Mabee's salamander was listed as a ST species in 1987. This is a relatively small species, with adults ranging from 8-12 centimeters, with a small head and long slender toes. The coloration is dark browngray to black with silvery white flecks that are abundant on the sides, but sparse on the back. The belly is light gray or gray-brown with a few flecks.

Known populations are low in number and tend to be isolated. Their range is restricted to the lower Coastal Plain of the Carolinas and Virginia. This species is known to occur in six localities in the coastal plain in extreme southeastern Virginia: one each in the Cities of Hampton and Suffolk and the counties of York, Southampton, Gloucester, and Isle of Wight. It is also found in the City of Newport News. The species is considered highly threatened, primarily by urbanization through the destruction of the sensitive habitat areas.

The species are found in savannas in burrows at the edges of bogs or ponds and in low wet woods and swamps. Breeding sites in Virginia are fish-free vernal ponds or ephemeral coastal plain sinkholes up to 1.5 meters deep, with surrounding forests generally composed of hardwoods mixed with pine. It is also found in low areas adjacent to coastal rivers and pine savannas, and in bogs, ponds, low wet woods, and swamps.

Eastern tiger salamander (Ambystoma tigrinum tigrinum) – State Endangered

The Eastern tiger salamander was listed as a SE species in 1987. This is Virginia's largest mole salamander reaching a maximum total length of 33-35 centimeters. It is a robust species with a broad head with relatively small eyes and an extremely long tail comprising approximately half of the total length. The back is dark brown to black with olive-yellow to brownish-yellow spots or blotches on the

back, sides, and belly. The blotches continue laterally and blend into the olive-yellow center creating a jagged- edged lateral line.

According to VDGIF, this native Virginia species may be more abundant than it appears due to its reclusive nature, although it is very restricted in Virginia. Four Virginia sites are known: one each from York, Mathews, Hanover, and Augusta Counties. However, potential breeding habitat around the York County site has been destroyed and the Hanover County site was known to have a large fish population and is probably extirpated. Therefore, this species can be considered extant in only two sites in Virginia – Mathews and Augusta Counties.

Breeding habitats include limestone sinkhole ponds and Coastal Plain vernal pools associated with wetlands. The terrestrial habitat is only generally described as that with a substrate suitable for burrowing, or sandy areas near shallow pools, chiefly in pine savannas. Unique habitat associations include springs and seeps, vernal pools, bottomland hardwoods and freshwater wetlands. They may inhabit any type of woodland or marshy grassland and are found in leaf letter, debris and humus.

Loggerhead sea turtle (Caretta caretta) – Federal Threatened/State Threatened

This large sea turtle has a carapace that is heart shaped, without striations on the surface, and brown to reddish brown in color. The plastron (lower shell) is hingeless, smaller than the carapace (upper shell), and cream to yellowish in color. Star-shaped light and dark streaks may be present on the carapace. The top of the head, the neck, and the front of the fore-flippers are reddish brown. The snout is short and the upper jaw is yellowish brown. The entire undersurface, side of the neck, and parts of the flippers are cream to yellow.

The Loggerhead is the most abundant sea turtle in Virginia's coastal waters. It is found only in salt water, in the Chesapeake Bay from Baltimore south, in all the major rivers along Virginia's coast, and into channels between barrier islands. This species is a wanderer which prefers moderately deep bays, and has been found in streams, marshes and many miles into the sea. The Chesapeake Bay is an important summer foraging area for subadults between the ages of 5 and 15 years. Nearly all nesting sites are on barrier islands in the United States. Nesting habitat is a sand beach that is high enough that it is not inundated by high tides nor soaked by groundwater rising from below. The Loggerhead forages in the bay and its estuaries primarily for horseshoe crabs. It would also consume other crustaceans, sea grasses, sponges, fish, mollusks, and snails.

According to VDGIF, there have been known occurrences of the Loggerhead sea turtle in York County and the Cities of Hampton, Norfolk, and Newport News.

Potential Impacts and Mitigation Measures

No-Build Alternative

The No-Build Alternative would not involve any project-related construction or changes to the natural environment. As a result, project-related environmental effects from the No-Build Alternative are not anticipated.

Build Alternatives

All of the Build Alternatives have the potential to affect threatened or endangered species or habitats along the study area corridor. The habitat of two species, the Mabee's salamander (near mile markers 244 and 260.5) and the Canebrake rattlesnake (near mile markers 256.5 and 258.5), was identified within the immediate vicinity of the study area. Each Build Alternative intersects the identified mapped habitat areas for these species. For projects affecting the Mabee's salamander, the VDGIF typically recommends maintaining an undisturbed naturally vegetated buffer of at least 300 meters around the identified habitat pond. In addition, any impact to the habitat (pond) automatically infers an impact to the species. For the

Canebrake rattlesnake, recommendations may include practices such as education requirements for the construction contractors and the installation of passageways under road systems. The potential presence of both species would require close coordination with the regulatory agencies and potential survey/assessment and design considerations.

The study also identified areas of potential habitat for the small whorled pogonia within the Alternative limits. As a federally listed threatened plant, prior to the issuance of a permit, the permittee must demonstrate that the species would not be harmed. A habitat survey conducted by a certified specialist would likely be required for this species as part of the project permitting process. While habitat surveys can be performed throughout the year, the detailed species survey, which must be conducted by a USFWS approved professional, must be completed between May 25th and July 15th of a given year and submitted to the agencies for their review and recommendations.

Eleven Bald eagle nests were identified within the two mile radius of the study area corridor, which require special coordination with the regulatory agencies, with possible construction time-of-year restrictions. However, all of the nest locations were located outside of the 660-foot nest protection zone, and there are no anticipated impacts to this species.

One occurrence of the Peregrine falcon was identified near the western study termini, in downtown Richmond. The buffered limits of the habitat are approximately 350 feet from the study area corridor. The VDGIF typically recommends a time-of-year restriction for construction activities within 600 vertical feet of the nest. Therefore, there is not an anticipated impact to this species.

The presence of federal and state threatened or endangered species, including those listed above, in the vicinity of the study area requires special consideration and coordination with various federal and state agencies at all stages of the project. Through the coordination with these agencies, potential impacts to target species and their habitats can be evaluated and avoided by implementing various practices as part of the project design. Examples of mitigation measures to avoid impacts to threatened and endangered species and their habitats which may be employed include shifting alignment to avoid potential areas, spanning/bridging resources and the use of bottomless arch culverts, countersinking of culverts, limiting clearing of existing vegetation to the greatest extent possible, strict adherence to erosion and sediment control guidelines and the implementation of stormwater best management practices, and adherence to maintaining applicable buffer widths to a species habitat. In addition, as noted above, construction time-of-year restrictions may be required for a given species.

Every attempt should be made to incorporate the preliminary recommendations into the design as much as possible. However, certain recommendations may not be practicable. Specific agency coordination should conducted during the final design and permitting stage of the project at which time more detailed agency recommendations would be determined.

As the project progresses, additional coordination would be required with the appropriate agencies for all species identified within the two mile radius of the study area corridor. If impacts cannot be avoided, time-of-year restrictions for construction may be required and these restrictions would be determined through the permitting process. In addition, a Section 7 consultation (in accordance with the ESA) may be required for a species if impacts can not be avoided. Also, habitat assessments and species surveys may be required to determine the presence of a threatened or endangered plant species or habitat. These species surveys must be completed by an agency certified or approved specialist, and may have restrictions on time-of-year when the surveys can be conducted.

K. Terrestrial and Aquatic Habitat and Wildlife

Methodology and Existing Conditions

The presence of federal and state identified habitat areas or specific wildlife resources in the vicinity of the study area require special consideration and coordination with the various federal and state agencies throughout project development. Although parklands and other natural areas are present throughout the corridor, sections of the corridor, particularly near the Cities of Richmond, Newport News, and Hampton, are highly urbanized where most natural resources have been altered during years of landscape manipulation for development. However, within the central section of the corridor, there are a number of undisturbed and/or highly naturalized areas in the vicinity of the study area. Despite the many years of disturbance that has diminished the extent and quality of the natural habitat within the corridor, there remains a number of natural resources that enhance the area. Many of these resources, summarized below, are found throughout the corridor and are regulated by a number of different federal and state agencies.

A variety of upland forest communities and diverse tidal and freshwater wetlands and stream systems are found in the Coastal Plain physiographic province in Virginia. The upland forests that originally covered much of the Virginia Coastal Plain have been extensively cleared or altered, making it difficult to determine which species and natural communities were once naturally prevalent. Much of the contemporary forest consists of successional or silvicultural stands of loblolly pine (*Pinus taeda*) and secondary pine-hardwood forests that have developed after repeated timbering or agricultural abandonment. The most mature remnant stands on mesic uplands are typically characterized by associations of American beech (*Fagus grandifolia*), several oaks (*Quercus* spp.), and American holly (*Ilex opaca var. opaca*). Patches of drier oak-dominated forest and steep bluffs with dense forests of chestnut oak (*Quercus montana*), beech, and mountain-laurel (*Kalmia latifolia*) are fairly common in the dissected inner Coastal Plain, especially north of the James River.

Streams and wetlands of the Coastal Plain are extensive and support a great variety of natural communities. The diversity of wetlands in this region spans a range of freshwater to saline, lunar-tidal estuaries; tidal and palustrine swamps; non-riverine, groundwater-saturated flats; seasonally flooded ponds and depressions; seepage slope wetlands; and various tidal and non-tidal aquatic habitats. Tidal Freshwater Marshes and Tidal Hardwood Swamps occur only along the James River and estuarine rivers to the north.

Specific terrestrial and aquatic habitat and wildlife conditions and concerns are noted throughout this report, and some features are expanded below. The majority of the study area is located within the existing, previously disturbed right of way of the roadway corridor. Within the study area, there are a number of wetlands and other WUS systems that were identified within the study area boundary through either a desktop review or field analysis as detailed in Section D above. As noted in Section L (below), due to the mode of transport by various types of vehicles traveling the corridor, both aquatic and terrestrial exotic and invasive species are very common along the roadway.

The following are specific terrestrial and aquatic habitat and wildlife resources reviewed by federal and state agencies in Virginia.

1. Anadromous Fish Use Areas

Anadromous fish are those migratory fish species which spend most of their lives in the sea and migrate to fresh water to breed. One of VDGIF's roles is to document both confirmed and potential Anadromous Fish Use Areas throughout Virginia. Anadromous fish have historically played an important economic role in Virginia. According to VDGIF, over the past few decades, monitoring has noted that anadromous fish populations such as shad and herring are severely depressed. The Commonwealth is actively addressing this decline and taking steps to restore the migratory pathways of the species. Through these

efforts, the Commonwealth is hopeful that the anadromous fish populations eventually return to, or near, historic levels with fish passage, supplemental stocking, and a harvest moratorium all contributing to the recovery. This population increase would have important recreational and commercial impacts. Many of these species also contribute to the food chain as forage for predatory fish and provide a marine-based energy source to freshwater systems.

The VDGIF maintains a database that identifies stream reaches that are confirmed or potential migration pathways, spawning grounds, or summer areas for anadromous fish. The species included in the VDGIF assessment are Alewife (*Alosa pseudoharengus*), Blueback herring (*Alosa aestivalis*), American shad (*Alosa sapidissima*), Hickory shad (*Alosa mediocris*), Striped bass (*Morone saxatilis*), and some populations of Yellow perch (*Perca flavescens*). Upstream boundaries are established at either migratory impediments, such as dams, or where habitat becomes unsuitable.

Based on information generated from the VFWIS, the VDGIF has identified the following (summarized in **Table 27**) Confirmed and Potential Anadromous Fish Use Area designations within a two mile radius of the study area corridor. These were identified due to the documented occurrence of anadromous and/or semi-anadromous fish species within, and/or adjacent, to various portions of the study area. The Potential and Confirmed Anadromous Fish Use Areas are included on the mapping in **Appendix K**.

Table 27: VFWIS Documented Anadromous Fish Use Areas within a Two Mile Radius of the Study Area

Status	Major River Basin	Study Area Corridor Locality	Stream Name (VDGIF ID)	Confirmed Species
		James City	Diascund Creek	Blueback herring, Striped bass, Yellow perch
	James	Richmond, Henrico County	James River (2)	American shad, Blueback herring, Striped bass, Yellow perch
		York County	Halfway Creek	Yellow perch
Confirmed	Confirmed	James City County, Newport News, Hampton	James River 1	Alewife, American shad, Blueback herring, Hickory shad, Striped bass, Yellow perch
		James City County	France Swamp	Yellow perch
	York	James City County	Ware Creek	Alewife, Blueback herring
	TOIK	York County	York River	Alewife, American shad, Blueback herring, Hickory shad, Striped bass, Yellow perch
		York County	Jones Millpond Creek	
	York	York County	King Creek	
	TOIK	York County	Queen Creek	
Potential	Potential	York County	Carter Creek	
1 Otential		York County	Skimino Creek	
		Newport News	Warwick River	
	James City County, Newport News Skiffes Creek			

The NMFS NOAA division also oversees anadromous and diadromous fish resources. This organization has not provided any official comments to date. However, based on information on the divisions website (http://www.nmfs.noaa.gov/pr/species/fish/), both Alewife and Blueback herring were listed as both a Candidate Species and a Species of Concern. A Candidate Species is a species that is undergoing a status review that NMFS has announced in a *Federal Register* notice, and is being considered for listing under the ESA as an endangered or a threatened species, but not yet the subject of a proposed rule. A Species of Concern is a species which the agency has some concerns regarding status and threats, but for which insufficient information is available to indicate a need to list the species under the ESA.

In addition to the database search, direct coordination was also initiated with the NMFS NOAA staff to discuss the potential for species to be located within the vicinity of the project corridor which were not yet included in the database. The Atlantic sturgeon (*Acipenser oxyrhinchus oxyrhinchus*) was listed as FE on February 6, 2012. However, this species has not yet been included in the agencies database. Through communication with the NMFS NOAA staff, this species has been identified within the York River and it's tributaries.

2. Colonial Water Birds

According to the CCB, Colonial Water Birds (also referred to as Colonial Wading Birds or Colonial Nesting Birds) include herons, egrets, ibises, gulls, terns, skimmers, cormorants, and pelicans. These birds share the unusual characteristic of nesting in dense assemblages, with the result of this behavior being that they typically breed in very few locations. The loss of these breeding areas may have profound consequences on a population level. In addition, due to their position in the aquatic food web, they are considered to be good indicators of ecosystem health. The most substantial threats to Colonial Water Birds include human disturbance, predation, habitat loss, and contaminants. Protection of sensitive colonies clearly depends on the availability of timely information of the birds locations. Development of strategic management plans to protect these species and breeding areas requires a broader understanding of population trends. Both the VDCR and VDGIF comment on a project's effect on this resource.

Through the project scoping process, the VDCR identified one natural heritage resource denoted as an Animal Assemblage within a two mile radius of the study area corridor, as listed in the table in **Appendix J**. This Animal Assemblage was a Colonial Wading Bird Colony (with a Global rank of G5 and a state rank of S2) located at Beaverdam Creek.

A review of the VDGIF database identified a number of Colonial Water Bird designations within the two mile radius of the study area corridor. However, there were no colonies within the immediate vicinity of the corridor. The identified colonies were predominantly great blue heron (*Ardea herodias*) while great egret (*Ardea alba*) colonies were also fairly common. Six great blue heron colonies are located within a half mile of the study area corridor (south of the mainline near mile markers 217.5 and 221.5; north of the mainline near mile markers 221, 223.5, 229, and 229.5). Only one of these colonies is located within 500 feet of the study area (north of the mainline at mile marker 229.5). The colonies were found primarily along the Chickahominy River and France Swamp, but also noted along Beaverdam Creek, Diascund Creek, and Wahrani Swamp. Yellow-crowned night heron (*Nyctanassa violacea*) colonies were identified in smaller numbers, and a single least tern (*Sternula antillarum*) colony was identified within the vicinity of the study area. The least tern colony is located within a half mile of the study area south of the mainline near mile marker 256. The Colonial Water Bird designations located within a two mile radius of the study area corridor are included on the mapping in **Appendix K.**

3. Essential Fish Habitat

The Magnuson-Stevens Fishery Conservation and Management Act (as amended by the Sustainable Fisheries Act of 1996) require all federal agencies to consult with the NMFS, NOAA division, on all on all actions or propose actions that are permitted, funded or undertaken by the federal agency which may

adversely affect essential fish habitat (EFH). Any federal agency that takes an action that could adversely affect EFH by reducing the quantity or quality of habitat must work with NMFS to identify impacts and steps for conserving the habitat and reducing the impact of that action. As defined by NOAA, EFH includes all types of aquatic habitat—wetlands, coral reefs, seagrasses, rivers—where fish spawn, breed, feed, or grow to maturity. The review for EFH considers all lifecycle stages including adults, juvenile, larvae, and eggs.

The NOAA EFH on-line mapping systems were used to identify potential regulated resources within the vicinity of the study area corridor. Official comments from NMFS have not been received for this study.

According to NOAA's EFH Mapper v2.0 and EFH data inventory, one NOAA Habitat Area of Particular Concern (HAPC) was designated within the study area corridor. HAPCs are discrete subsets of EFH that provide extremely important ecological functions or are especially vulnerable to degradation. These areas are rare, particularly susceptible to human-induced degradation, especially ecologically important, or located in an environmentally stressed area. The HAPC designation does not confer additional protection or restrictions upon an area, but can help prioritize conservation efforts and federal actions with potential adverse impacts to HAPC would be more carefully scrutinized during the consultation process and would be subject to more stringent EFH conservation recommendations. According to NOAA's EFH Mapper v2.0 and EFH data inventory, a HAPC is designated for the Sandbar shark (Carcharhinus plumbeus) for all stages of the lifecycle throughout the eastern part of the corridor, from approximately just west of the Queen Creek crossing to the project termini in the City of Hampton. A number of additional EFH designations are identified in the vicinity of the project corridor according to the NOAA Guide to EFH Designations in the Northeastern United States on-line mapping system (http://www.nero.noaa.gov/hcd/index2a.htm). This guide provides a geographic species list of EFH designations completed by the New England Fishery Management Council, Mid-Atlantic Fishery Management Council, South Atlantic Fishery Management Council, and the NMF in the Northeastern United States. Species with designated EFH for at least one life cycle stage within the vicinity of the corridor include: Windowpane flounder (Scophthalmus aguosus), Bluefish (Pomatomus saltatrix), Atlantic butterfish (Peprilus triacanthus), Summer flounder (Paralichthys dentatus), Black sea bass (Centropristis striata), King mackerel (Scomberomorus cavalla), Spanish mackerel (Scomberomorus maculatus), Cobia (Rachycentron canadum), Red drum (Sciaenops occelatus), Dusky shark (Carcharhinus plumbeus), and Sandbar shark (Carcharhinus plumbeus). The database identified EFH habitat for all species listed above throughout the corridor, with the exception of the Windowpane flounder and the Dusky shark, whose EFH habitat is limited to approximately east of Williamsburg. A HAPC was also indentified in this database for the Sandbar shark, as noted above.

NOAA EFH Areas Protected from Fishing (APF) are areas in which the NMFS and the regional fishery management councils have used the EFH provisions established in Section 303(a)(7) of the Magnuson-Stevens Fishery Conservation and Management Act to prevent, mitigate, or minimize adverse effects from fishing on EFH. NMFS has not prohibited fishing in there areas, but steps such as anchoring restorations and gear prohibitions, have been taken to minimize the impact that fisheries have on EFH. According to NOAA's EFH Mapper v2.0 and EFH data inventory, while the James River and the York River are designated as Southern Fishing Management Areas to Hopewell and West Point, respectively, no EFH APF are designated for any waterway within the study area.

4. Natural Communities

The VDCR identifies resources considered natural heritage resources across the state. The VDCR identified a number of Natural Communities (which are considered natural heritage resources) within a two mile radius of the study area corridor. These Natural Communities, as listed in the table in **Appendix J**, include Mesic Mixed Hardwood Forest, Basic Mesic Forest, Piedmont/Coastal Plain Oak - Beech/Heath Forest, Coastal Plain Dry Calcareous Forest/Woodland, Oak/Heath Forest, Coastal Plain

Depression Wetland, Tidal Freshwater Marsh, Tidal Oligohaline Marsh, Coastal Plain/Piedmont Basic Seepage Swamp, and Non-Riverine Flatwood/Swamp. These natural community types may be located throughout the project corridor.

The Grafton Ponds Natural Area Preserve, which is owned by the City of Newport News but is under VDCR jurisdiction, is located in the study vicinity, but not within the study area corridor. The 375 acre Grafton Ponds Natural Area Preserve is located west of Exit 250, approximately 2,600 feet north of the mainline.

Grafton Ponds are listed as a Coastal Plain Depression Wetland Natural Community by the VDCR. While this Natural Community type has not yet been ranked by the state, according to the VDCR, Grafton Ponds represent Virginia's best remaining example of a coastal plain pond complex, and the state considers these rare wetland complexes as areas deserving high levels of protection from development. The features are formed from the dissolution of underlying calcareous marine deposits within the Yorktown formation. While the systems themselves are considered rare, they support several locally-rare or ST species including Harper's fimbristylis, Mabee's salamander, Pond spice, Cuthbert turtlehead, and Barking treefrog.

5. Submerged Aquatic Vegetation

The Virginia Institute of Marine Science (VIMS) at the College of William and Mary monitors and maintains a database for the presence and health of SAV in the Chesapeake Bay and its watershed. The organization also reviews projects for potential impacts to SAV resulting from that project. SAV beds filter polluted runoff, provide food for waterfowl, and provide habitat for blue crabs, juvenile rockfish, and other aquatic species. SAV beds not only indicate the presence of high water quality, their establishment helps to improve water quality in the area.

As part of the Annual SAV Monitoring Program, since 2001 VIMS has been orthorectifying aerial images that cover SAV beds. According to the VIMS SAV 2011 Interactive Map, while there are SAV beds documented in the James River and York River, and several major tributaries to these systems including the Chickahominy River, there are no SAV beds within the vicinity of the study area corridor.

To date VIMS has not provided comments as part of the scoping process for this project. In addition, no other agency or database search has provided information regarding SAV along the study area corridor.

6. Trout Waters, Threatened and Endangered Waters, Shellfish Areas

The VDGIF also tracks the presence of and reviews projects for impacts to trout, threatened and endangered waters, and shellfish areas throughout Virginia. Threatened and endangered waters are streams and rivers that contain documented occurrences of federal or state listed threatened or endangered species and their associated habitat. Trout waters include documented wild trout streams, stocked trout waters or recreational trout fisheries.

According to VDGIF VFWIS data, there are no trout waters, threatened or endangered waters, or shellfish areas in the vicinity of the study area.

Potential Impacts and Mitigation Measures

No-Build Alternative

The No-Build Alternative would not involve any project-related construction or changes to the natural environment. As a result, project-related environmental effects from the No-Build Alternative are not anticipated.

Build Alternatives

All of the Build Alternatives have the potential to impact terrestrial and aquatic habitat or species along the study area corridor. Extensive coordination with the different agencies should continue throughout all stages of project development to reduce potential impacts to these resources. In addition, avoidance and minimization of potential impacts to the natural environment and wildlife should be considered throughout the design and construction phases of the project. Permitting of the project would also address avoidance, minimization, and compensatory mitigation measures, as needed.

All of the Build Alternatives specifically have the potential to impact unique wildlife resources including Anadromous Fish Use Areas, EFH, and Colonial Water Birds. However, as specifically discussed below, the impacts would be negligible following the measures outlined in the following sections.

Terrestrial Wildlife and Habitat

Because the Build Alternatives consist of widening along an existing corridor, the proposed activities would not likely affect any substantial forest resource. Because the proposed Build Alternatives follow an existing highway corridor, and much of the corridor is already within an urbanized or developed area, impacts to terrestrial habitat would be limited to the displacement of small sections of remaining, often disjunct, non-contiguous tracts of forests. The existing corridor poses a barrier to wildlife movements that would not be substantially altered by the proposed Alternatives. The threat of mortality or injury to wildlife within the corridor would persist but would not likely increase in any measurable amount due to the improvements.

Potential exists for temporary impacts to wildlife with the displacement of vegetated cover within the construction footprint. The mechanical removal of cover would cause animal migration away from the disturbance resulting in temporary decrease in habitat usage by mostly common edge-dwelling species. Construction activities may also result in wildlife mortality. Foraging behaviors and wildlife use may also be associated with slope stabilization practices, but would only be on a temporary basis.

VDCR Natural Communities noted above are not anticipated to be impacted by any of the Build Alternatives to any measurable degree.

As part of the construction practices, the removal of existing vegetation should be avoided to the greatest extent practicable to minimize potential impacts to the terrestrial system. In addition, all measures to reduce the construction footprint, in general, should be followed as part of the final design. Cut and fill should be minimized to the greatest extent practical to ensure structural stability of the roadway and associated structures. Particularly in areas of environmental concern, steeper than conventional slopes should be considered as part of the design. In addition, the implementation of best management practices for erosion and sediment control and the abatement of pollution loading would minimize potential impacts to adjoining habitats and communities.

To avoid attraction of species to the edge of the roadway, VDOT should consider excluding landscaping options which intentionally provide wildlife habitat or attract wildlife, such as those species with high feeding values. Where feasible, passageways for terrestrial wildlife should be provided and maintained beneath proposed bridges and any elevated structures to help minimize effects of wildlife corridor bisection. Fencing should also be considered to minimize motorized collisions with wildlife and to help direct wildlife towards any maintained passageways.

Additional measures to prevent the colonization of invasive species are discussed in Section L.

Aquatic Wildlife and Habitat

All of the Build Alternatives would reduce aquatic habitat within the corridor to a small degree. The extension of culverts could lead to the direct loss of fish and macroinvertebrates within the construction zone and would permanently alter the available habitat in the impacted areas. However, these areas would likely be colonized again, following the construction activities. There is the potential for increased water quality degradation from stormwater runoff due to the increase in impervious surface affecting overall water quality. However, the relatively small impervious impact that may occur is unlikely to affect the aquatic habitat or the makeup of biological communities to any appreciable degree and best management practices would be employed to reduce potential impacts.

The presence of natural areas and federal and state listed natural habitat and unique wildlife resources in the vicinity of the study requires special consideration and coordination with various federal and state agencies. Through the coordination with these agencies, potential impacts to target species and their habitats can be evaluated and avoided by implementing various practices as part of the project design. Examples of mitigation measures which may be employed to avoid impacts to wildlife and their habitats include shifting alignment to avoid potential areas, spanning/bridging resources and the use of bottomless arch culverts, countersinking of culverts, limiting clearing of existing vegetation to the greatest extent possible, the strict adherence to erosion and sediment control guidelines and the implementation of stormwater best management practices, and the adherence to maintaining applicable buffer widths to a species habitat.

In general, if impacts cannot be avoided, time-of-year restrictions for construction may be required and these restrictions would be determined through the permitting process. Also, habitat assessments and species surveys may be required to determine the presence of a threatened or endangered plant species. These species surveys must be completed by an agency certified or approved specialist, and may have restrictions on the time-of-year when the surveys can be conducted. Recommendations and practices for specific resources are detailed below.

All Build Alternatives cross Queen Creek near mile marker 239.5. However, the VDGIF has identified this system as a potential anadromous fish use area, and not a confirmed area. Through the permitting process, the VDGIF may recommend for anadromous fish use areas (or their tributaries which cross the study area corridor) the following time-of-year construction restrictions (meaning no in-stream work is permitted during these dates during a given year): 1) James River and tributaries time-of-year restriction from February 15th to June 30th; and 2) York River and tributaries time-of-year restriction of February 15th through June 15th. In addition to potential time-of-year construction restrictions to minimize impacts to anadromous fish resources, the VDGIF also typically recommends the following activities: using non-erodible cofferdams to isolate the construction area; blocking no more than 50% of the streamflow at any given time; stockpiling excavated material in a manner that prevents reentry into the stream; revegetating barren areas with native vegetation; and implementing strict erosion and sediment control measures. In regards to stream crossings, the agency recommends clear-span bridges. If, however, clear-span bridges are not feasible, they suggest that the culverts should be countersunk at least six inches below the stream bed or, alternatively, bottomless culverts should be installed to allow passage of aquatic organisms.

VDCR Natural Communities, including the Grafton Pond Natural Area Preserve are not anticipated to be impacted by any of the Build Alternatives to any measurable degree. The agency may require a survey of the area for the presence of Grafton ponds or species associated with these systems. The agency would likely recommend avoiding any direct impact to these resources, and if a pond is identified in the vicinity of the study area corridor, providing a buffer area from the resource. In addition, the agency would likely recommend the strict adherence to erosion and sediment control measures. These recommendations would be provided during the permitting phase of the project.

As noted above, several EFH and one HAPC are noted for the corridor. In order to minimize impacts to these resources, the NMFS may require specific time-of-year construction restrictions which would limit construction activities within a specific channel, the strict adherence to erosion and sediment control measures, the immediate stabilization and restoration of disturbed areas, and mitigation measures such as the use of bubble curtains to reduce sound/pressure waves which may potentially negatively impact a fish species. A formal consultation with the agency may also be required. The agency's formal recommendations would be made during the permitting process for the project.

No Build Alternative directly impacts any Colonial Water Bird resource. According to the VDGIF, line of sight distance is the primary factor in determining potential impacts of a construction project to Colonial Water Birds. One half mile is the standard line of sight distance reviewed by the agencies. As the distance decreases, noise may also become a factor. As noted above, six Great blue heron colonies are located within a half mile of the study area corridor, with one of these colonies located within 500 feet of the study area. In addition, a single Least tern colony is located within half mile of the corridor, south of the mainline. Through the permitting process, the VDCR and VDGIF may recommend a number of specific practices to minimize and mitigate for potential impacts to these resources. Typical requirements include the direct avoidance of a colony, shifting the alignment away from the resource to reduce the distance of the construction to the colony, and the strict adherence to erosion and sediment control measures. Surveys and time-of-year restrictions for construction practices may also be required. For a Great blue heron, VDGIF typically recommends a time-of-year restriction from February 15th through July 31st for construction within 0.25 mile of a rookery or within 0.5 mile of a rookery if the project involves high density activity. In addition, the agency typically recommends perpetually maintaining an undisturbed naturally vegetated buffer of at least 500 feet around the rookery.

Additional measures to prevent the colonization of invasive species are discussed in Section L.

L. Invasive Species

As defined by VDCR, an invasive species is a non-native (alien, exotic, or non-indigenous) plant, animal, or disease that causes or is likely to cause ecological and economic harm to the natural system. The threat of invasive species to Virginia's natural communities has greatly increased over the years due to a number of factors including rapid globalization, international trade activity, and increased travel between different states and regions within Virginia. Introduction of an invasive species to a natural habitat can either be intentional (such as ornamental plants for gardens, erosion control, food for both livestock and people, pets, etc.) or accidental (species in ship ballast water, shipping crates, mixed in with plant materials from other parts of the world, and attached to travelers' vehicles and personal belongings).

1. Invasive Plant Species

Methodology and Existing Conditions

The VDCR-DNH, in association with the Virginia Native Plant Society, have identified and listed invasive plant species that threaten Virginia's natural populations. To date, they have listed over 100 plant species that threaten or potentially threaten natural areas, parks, and other lands. Invasive species are also classified by levels of invasiveness, including High, Medium, and Occasional based on a number of factors including the cumulative impact on natural areas, the potential to disperse and invade natural areas, distribution and abundance, difficulty of management, and impacts on other species. Highly invasive plant species generally disrupt ecosystem processes and cause major alterations in plant community and overall structure. They can easily establish in undisturbed habitats and would colonize disturbed areas rapidly under the appropriate conditions. While plants with medium and low invasiveness can become management problems, they tend to have minor adverse effects to the natural system and are more easily managed.

Using the DCR-DNH information, **Table 28** includes plant species that are considered highly invasive and are common to the general area of the study corridor. These species have the potential to become established in the study area corridor, particularly in disturbed areas generated during roadway construction.

Table 28: Potential Highly Invasive Plant Species along the Study Area

Layer	Common Name	Scientific Name
Tree	Tree-of-heaven	Ailanthus altissima
	Autumn olive	Elaegnus umbellate
Shrub	Chinese privet	Ligustrum sinense
	Multiflora rose	Rosa multiflora
	Japanese honeysuckle	Lonicera japonica
Vine	Kudzu vine	Pueraria montana
	Oriental bittersweet	Celastrus orbiculata
	Aneilema	Murdannia keisak
	Wine berry	Rubus phoenicolasius
	Canada thistle	Cirsium arvense
	Chinese yam	Dioscorea oppositifolia
	Common reed	Phragmites australis
	Japanese knotweed	Polygonum cuspidatume
	Japanese stilt grass	Microstegium vimineum
Herbaceous	Johnson grass	Sorghum halepense
Herbaceous	Spotted knapweed	Centaurea biebersteinii
	Lesser celandine	Ranunculus ficaria
	Cogon Grass	Imperata cylindrica
	Purple Loosestrife	Lythrum salicaria
	Parrot feather	Myriophyllum aquaticum
	European water milfoil	Myriophyllum spicatum
	Alligator Weed	Alternanthera philoxeroides
	Hydrilla	Hydrilla verticillata

The highly disturbed nature of highway corridors, in addition to the easy mode of transport by the vehicles traveling the corridor, including vehicles from other regions (both local and national), allows for the establishment of exotic and invasive species. As summarized in **Table 29**, stands of several aquatic and terrestrial invasive, non-native, exotic, or "nuisance" plant species were identified within the study area including, Tree-of-heaven (*Ailanthus altissima*), Japanese stiltgrass (*Microstegium vimineum*), Common reed (*Phragmites australis*), and Common dodder (*Cuscuta gronovii*). The primary invasive species identified within the study area was Japanese stiltgrass (*Microstegium vimineum*).

Table 29: Invasive, Non-Native, Exotic, or Nuisance Plant Species Identified Along the Study Area

Location	Common Name	Scientific Name
West of Mile Marker 196; North of	Japanese stiltgrass	Microstegium vimineum*
Mainline	Japanese sungrass	Microsiegium vimineum
East of Mile Marker 204; South of Mainline	Japanese stiltgrass	Microstegium vimineum*
East of Mile Marker 208; South of Mainline	Japanese stiltgrass	Microstegium vimineum*
East of Mile Marker 212; South of Mainline	Japanese stiltgrass	Microstegium vimineum*
East of Mile Marker 221; South of Mainline	Japanese stiltgrass	Microstegium vimineum*

Location	Common Name	Scientific Name
West of Mile Marker 222; South of Mainline	Japanese stiltgrass	Microstegium vimineum*
Exit 234; Southwest Cloverleaf	Tree-of-heaven	Ailanthus altissima*
West of Mile Marker 247; North of Mainline	Common dodder	Cuscuta gronovii
East of Mile Marker 228; South of Mainline	Japanese stiltgrass	Microstegium vimineum*
East of Mile Marker 229; South of Mainline	Japanese stiltgrass	Microstegium vimineum*
West of Mile Marker 249; South of Mainline	Japanese stiltgrass	Microstegium vimineum *
East of Mile Marker 257; South of Mainline	Japanese stiltgrass	Microstegium vimineum*
Mile Marker 260.5;North of Mainline	Common reed	Phragmites australis*
East of Mile Marker 260; North of Mainline	Common reed	Phragmites australis*

East of Mile Marker 264; North of Mainline	Common reed	Phragmites australis *

^{*} Species listed on the VDCR Invasive Alien Plant Species of Virginia List

Potential Impacts and Mitigation Measures

No-Build Alternative

The No-Build Alternative would not involve any project-related construction or changes to the natural environment. As a result, project-related environmental effects from the No-Build Alternative are not anticipated.

Build Alternatives

Because the majority of the additional roadway associated with all of the Build Alternatives would be located within the existing disturbed corridor, the likelihood of an increase in the prevalence of invasive species would be expected to be minimal. However, because the clearing of vegetated areas would be necessary for this project, there would be opportunity for invasive species to become established due to extra light penetrating the forest canopy in addition to disturbed soils. In order to minimize opportunities for invasive species to become established, steps would be taken to limit the removal of native species throughout the corridor during construction. Contract bid packages could include special provision for managing invasive species that are specific to the appropriate sections of VDOT *Road and Bridge Specifications*. While the newly established right of way is vulnerable to colonization by invasive plant species from the existing highway and adjacent property, implementing special construction provisions would reduce the potential for establishment. No specific mitigation measures are required.

2. Invasive Animal Species

Methodology and Existing Conditions

A number of both aquatic and terrestrial animal species threaten the native plant and animal communities in Virginia. The following listing includes common species that could affect the study area if encountered within construction limits. None of these species were directly observed during field investigations.

The Virginia Administrative Code 4VAC15-20-160 (VDGIF) designates the following as nuisance species in Virginia: House mouse (*Mus musculus*); Norway rat (*Rattus norvegicus*); Black rat (*Rattus rattus*); Coyote (Canis latrans); Nutria (*Myocastor coypus*); Woodchuck (*Marmota monax*); European starling (*Sturnus vulgaris*); English (house) sparrow (*Passer domesticus*); Pigeon (Rock Dove) (*Columba livia*); and other non-native species as defined in the Migratory Bird Treaty Reform Act of 2004 and

regulated under 50 CFR 10.13. In addition, the DCR-DNH has identified a number of invasive species which threaten Virginia's wildlife and plant systems such as the Emerald ash borer (*Agrilus planipennis*), Northern snakehead fish (*Channa argus*), Rapa welk (*Rapana venosa*), and the Imported fire ant (*Solenopsis invicta*). These species are listed as established in Virginia.

The DCR-DNH have also identified Zebra mussel (*Dreissena polymorpha*), Sirex woodwasp (*Sirex noctilio F.*), Rusty crayfish (*Orconectes rusticus*), and Chinese mitten crab (*Eriocheir sinensis*) as species that may threaten Virginia's wildlife and plant systems; however, they are not identified as well established in the Commonwealth.

Potential Impacts and Mitigation Measures

No-Build Alternative

The No-Build Alternative would not involve any project-related construction or changes to the natural environment. As a result, project-related environmental effects from the No-Build Alternative are not anticipated.

Build Alternatives

Because the Build Alternatives would involve limited widening along an existing disturbed corridor, the addition of invasive animal species is expected to be minimal due to the project. Contract bid packages should include special provision for managing invasive species that are specific to the appropriate sections of VDOT *Road and Bridge Specifications*. No specific mitigation measures are required.

M. Navigation

Methodology and Existing Conditions

Through the scoping process, the United States Coast Guard (USCG) identified two bridge crossings which may require a detailed review by their agency. These areas included the bridges over Queen Creek east of Exit 238 (Colonial Williamsburg) in York County and Newmarket Creek near the study termini in the City of Hampton. The agency requested information concerning the number and type of vessels that utilize these two waterways in the vicinity of the bridges.

According to the information provided from the VDGIF Boating Division, for the City of Hampton, there are 4,299 boats listed as being "primarily used" in the City and 421 Personal Water Crafts (PWCs) registered from the City. For York County, there are 3,064 boats listed as being "primarily used" in the County, and 468 PWCs registered from the County.

According to the NOAA Tide Chart No. 12243, the vertical clearance of the Queen Creek bridges is 15 feet and the horizontal clearance is 40 feet. Queen Creek is approximately 4.5 feet deep at this location. There is no NOAA tide information for Newmarket Creek based on the system's inland location. `However, based on VDOT bridge inspection reports, the vertical clearance is less than 6 feet, with the water depth less than 4 feet at this location. The horizontal clearance is approximately 40 feet.

Through discussions with the local VDGIF Conservation Police Officer, local marina owners, and the staff of Bluebird Gap Farm in the City of Hampton (which is a park located just downstream of the I-64 Newmarket Creek bridge), the vessel traffic is minimal in both areas, consisting of small, flat-bottom vessels such as canoes and kayaks. Occasionally, there may be a small john boat utilizing the area but this occurrence is very infrequent.

For Queen Creek, this area is highly limited in use based on the tides and depth of the water, and the vertical clearance of the bridge. Most of the traffic stops downstream, at the docks/facilities at Queens Lake. The area at the bridge and upstream is primarily used by local citizens, in either canoes or kayaks

who are boating for sightseeing/fishing purposes. Small john boats are occasionally observed in the area, particularly during duck hunting season.

While many larger vessels utilize the Back River, these boats can not venture upstream to access Newmarket Creek. In comparison to Queen Creek, Newmarket Creek is even less utilized by vessels. Boats that do enter Newmarket Creek, including the smaller boats such as canoes and kayaks, tend to stop at Air Power Park near Mercury Boulevard. This limited use is not only due to the tides and the limited depth of water for the entire reach, but also due to the major impediments within the channel. These impediments include utility crossings and protective features at Armistead Avenue and a large weir that is located just downstream of I-64, at the confluence of Coliseum Lake. This weir spans nearly the entire channel.

Potential Impacts and Mitigation Measures

No-Build Alternative

The No-Build Alternative would not involve any project-related construction or changes to the natural environment. As a result, project-related environmental effects from the No-Build Alternative are not anticipated.

Build Alternatives

The USCG requires a bridge permit for the construction of a new bridge or causeway, or reconstruction or modification of an existing bridge or causeway across navigable waters of the United States. This authority is derived under the General Bridge Act of 1946, as amended, the Rivers and Harbors Act of 1899, as amended, and the Act of March 23, 1906, as amended, all require that the location and plans of bridges and causeways across the navigable waters of the United States be submitted to and approved by the Secretary of Transportation prior to construction. The purpose of the Bridge Permit is to preserve the public right of navigation and to prevent interference with interstate and foreign commerce.

For all of the Build Alternatives, the USCG would review the proposed bridges over Queen Creek in York County and Newmarket Creek in the City of Hampton. As outlined above, vessel use at these crossing is extremely low and limited to small vessels such as canoes and kayaks.

At this time, it is expected that the new bridges would be of the same elevation as the existing; however, this would be determined as part of the final design of the project. Based on the likely design and the limited use of small vessels, a bridge permit from the USCG is not anticipated; however, this determination would be made by the USCG during the permitting process.

III. Regulatory Anticipated Permits and Clearances

The construction of any of the Build Alternatives would require coordination with and approval/clearances from a number of different regulatory and advisory agencies during the final design and permitting phase of the project. Anticipated primary federal, state, and local, natural resources related permits, approvals, and clearances for any of the Build Alternatives are summarized below. These review and coordination efforts are also discussed in Section II of this memorandum.

A. Water Related Permits and Clearances

The USEPA has regulatory oversight of the Corps CWA permitting. In addition, under the NEPA regulations and CEQ Guidelines, the USEPA is also charged with review responsibilities of NEPA documents to ensure proposed activities utilizing federal funds are, in part, protecting water quality and special aquatic sites including sanctuaries and refuges, wetlands, mudflats, vegetated shallows, and riffle and pool complexes, as defined in the USEPA's 404(b)(1) Guidelines for Specification of Disposal Sites for Dredged or Fill Material (33 U.S. Code Annotated §1344 *et seq.*; 40 CFR 230). The Corps applies the

USEPA Section 404(b) (1) Guidelines rather than deferring to the USEPA's review of their application. Therefore, the USEPA Guidelines establish a presumption against filling special aquatic sites by prohibiting the discharge of dredged or fill material into waters if there is a practicable alternative to the proposed discharge which would have less adverse impact on the aquatic ecosystem. During permit coordination with regulatory agencies, an alternatives analysis is often required generally because the Guidelines contain a presumption that less damaging alternatives are presumed to be available.

The Corps administers regulations for activities affecting waters of the United States and navigable waters pursuant to Section 404 of the Clean Water Act of 1977, as amended, and Section 10 of the Rivers and Harbors Act of 1899, respectively. Section 9 of the Rivers and Harbor Act prohibits the construction of any obstruction, including dams, bridges, and causeways, across any navigable waterway without the approval of the Corps or USCG. Under the Corps regulations (33 CFR 329) as applied to the study area, navigable waters are determined by the District Engineer and are made for all waters that are "presently used or have been used in the past, or may be susceptible for use to transport interstate or foreign commerce". The Corps general definition of navigable waters of the United States is "those waters subject to the ebb and flow of the tide shoreward to the mean high water mark and/or are presently used, or have been used in the past, or may be susceptible for use to transport interstate or foreign commerce. A determination of navigability, once made, applies laterally over the entire surface of the waterbody, and is not extinguished by later actions or events which impede or destroy navigable capacity." This includes, by definition, all tidal waterbodies including streams/rivers and wetlands.

In addition to the Corps regulatory oversight, several state agencies have jurisdiction over surface waters. The VDEQ administers the Virginia Water Protection Permit program (9 VAC 25-210), Section 401 of the CWA, and the State Water Control Law for activities affecting jurisdictional wetlands, streams, and other water bodies. In July 2000, the VDEQ authority was modified by the Virginia General Assembly to develop a non-tidal wetlands program and to provide regulations to protect fish and wildlife resources. Section 401 of the CWA requires any applicant for a federal license or permit for any activity that may result in a discharge into waters to obtain a certification that discharge will not adversely affect water quality from the state in which the discharge will occur. Section 401 requires certification by Virginia that prospective permits comply with the state's applicable effluent limitations and water quality standards. While waters that are considered "isolated" do not fall under federal CWA permitting, they are regulated under the VDEQ.

The VMRC is authorized to permit activities in, on or over state-owned subaqueous lands in Virginia (Code of Virginia Chapter 2, Title 62.1). Through this regulatory framework permitted activities include building, dumping, or otherwise trespassing upon or over, encroach upon, take or use any material from the beds of the bays, oceans, and jurisdictional rivers, streams, or creeks. In addition, the VMRC is responsible for managing and regulating the use of Virginia's tidal wetlands and coastal primary sand dunes in conjunction with Virginia's local wetlands boards, where established. The VMRC also protects and regulates those areas designated as non-vegetated and vegetated tidal wetlands and state-owned subaqueous bottom land.

Virginia's Waters of the United States, including wetlands, are also regulated under the Virginia Wetlands Act and through Subtitle III of Title 28.2 of the Code of Virginia. Through this framework, the County's Local Wetlands Board regulates activities in tidal wetlands within their Counties. However, because this project is a government project, the local wetlands boards do not have jurisdiction over impacts to tidal wetlands and has deferred all jurisdictions regarding this project to the state (VMRC).

The federal and state guidelines require that no discharge of dredged or fill material in waters of the United States be permitted unless appropriate and practicable steps have been taken to minimize adverse impacts associated with the discharge. Additional federal and state guidance and policy documentation

assist in defining the requirements for mitigation (which includes avoidance, minimization, and compensation). Compliance with these requirements is an essential environmental safeguard to ensure that CWA objectives for the protection of streams and wetlands are achieved.

Prior to the development of the final design, a jurisdictional determination must be obtained by the Corps. Once this determination is prepared, the type of and quantity of impacts to jurisdictional surface waters can be assessed and permitted. The mitigation measures for these stream and wetland impacts would be identified for any of the Build Alternatives during the final design. These measures would include avoidance and minimization efforts to the greatest extent practicable, including but not limited to the following practices:

- The use and appropriate placement of erosion and sediment control measures and best management practices.
- The use of upgraded erosion and sediment controls in environmentally sensitive areas.
- Bridging/spanning of streams and wetlands.
- Alignment shifts around specific systems.
- The use of cofferdams; steepening of slopes and the use of retaining walls on steeper slopes.
- Bottomless arch culverts and properly countersunk culverts.
- Stream relocation to improve skew angle and shorten culverts if new culverts are necessary.
- Ensuring groundwater recharge/wetland hydrology maintenance through the location of outfalls and infiltration trenches.

Following construction practices, any additional stormwater generated through new impervious surfaces would be treated through improved stormwater management systems.

The federal and state permit programs rely on the use of compensated mitigation to offset unavoidable aquatic impacts by replacing lost functions with replicated functions elsewhere. Appropriate mitigation is determined by the agencies and is conducted on a case-by-case basis; however, the process is based on established policies, guidelines, and regulations.

Compensatory mitigation would likely be required for permanent impacts to stream and wetlands resulting from the project activities. Compensatory mitigation is typically required in the same or adjacent HUC within the same watershed and physiographic province as the impact. As part of the permitting process, mitigation options would be investigated using the various agency resources including the July 2004 Joint Corps and the VDEQ *Recommendations for Wetland Compensatory Mitigation:*Including Site Design, Permit Conditions, Performance Criteria, and Monitoring Criteria and the associated Mitigation Checklist, as well as the March 2008 Offsite Mitigation Guidelines. Of greatest significance, on April 10, 2008, new regulations providing guidance for compensatory mitigation was jointly issued by the Corps and the USEPA. The new mitigation rule, which became effective June 9, 2008, changed the federal permitting preference regarding how compensatory mitigation is accomplished for project impacts to jurisdictional surface waters. This rule does not change when compensation is required.

The new rule provides the following preference for compensatory mitigation options:

- 1. Purchase of compensatory mitigation bank credits.
- 2. Purchase of an approved in-lieu fee fund credits.
- 3. Watershed approach based mitigation by the permittee.
- 4. On-site mitigation/in-kind mitigation by the permittee.
- 5. Off-site mitigation/out-of-kind mitigation by the permittee.

Both the Corps and the VDEQ have currently adopted this hierarchy of compensatory mitigation options for permanent impacts to jurisdictional surface waters. There are currently a number of compensatory mitigation banks that have the appropriate available credits for the potential impacts. The final compensatory mitigation option would be determined during the project's permitting process.

The compensatory mitigation requirements for both streams and wetlands would be determined for the selected Build Alternative during the permitting phase. The current typical compensatory mitigation to impact ratios for non-tidal forested, scrub-shrub, and emergent wetlands are 2:1, 1.5:1, and 1:1, respectively. The compensatory mitigation to impact ratio for tidal emergent wetlands is determined on a case-by-case basis; however, 2:1 is typical for these systems.

Compensatory mitigation is not typically required for open water impacts (e.g., piers in open waters) but this requirement would be reviewed on a case-by-case basis. In addition, compensatory mitigation is typically required for unavoidable stream impacts to greater than 300 linear feet of stream at a crossing. However, this determination would be made on a project-by-project basis and due to the scale of this specific project, this threshold may be waived. The approved assessment methodology to determine the required stream compensation would be completed as part of the compensatory mitigation plan. As detailed above, at the time of this document, the approved assessment methodology is the USM. All potentially impacted channels would need to be assessed and the USM methodology completed in full to determine the compensatory mitigation requirements for the project. Compensatory mitigation for tidal stream systems would be determined on a case-by-case basis. At this time, compensatory mitigation is not typically required for impacts to jurisdictional ditches. The requirements for compensation for jurisdictional ditch impacts would be determined during the permitting process.

In accordance with the existing regulations and standard permit conditions, all temporary impacts would also be required to be restored to their original contours and re-vegetated with the same or similar species. Additional compensatory mitigation other than previously stated for temporary impacts is typically not required through the permitting process.

To continue the permitting process detailed above, the Joint Permit Application (JPA) must be prepared and submitted for agency review. It is important to have the defined construction limits finalized prior to completing the permit application to ensure that the appropriate impacts are addressed, thus avoiding the need to change either the permit application or the actual issued permit in the future if changes occur. Any changes after the initial JPA submittal would increase the agencies' review times and may require a modification to a permit if the permit is already issued. This is of particular importance since the actual amount of land disturbance and/or impacts determines the type of permit(s), and subsequent requirements, necessary. The VMRC serves as the "clearinghouse" for the JPAs, distributing the applications to the appropriate regulatory and advisory agencies.

The study team contacted the federal and state permitting agencies to discuss this project and the permits necessary for any potential impacts or activities. Coordination with the Corps, VDEQ, and VMRC would be required during the permitting phase of the project to determine the jurisdictional limits of surface waters and to make a final determination of the need for and type of permits. Both temporary and permanent impacts to jurisdictional wetland and stream systems from any of the Build Alternatives would require a permitting decision from these agencies. While the permit type(s) and requirements can not be determined until the JPA is submitted and reviewed, based on the scale of the project, the multiple individual impact area crossings and the potential for tidal impacts, it is anticipated that the permits to be issued for this project include a Section 404 Individual Permit from the Corps, a Virginia Water Protection Individual Permit from the VDEQ (which serves as the Section 401 certification), and a subaqueous bottomland permit from the VMRC (Virginia General Permit #1 if project is pursued by the VDOT) for any impacts to systems with drainage areas greater than five square miles. Wetland impacts

are exempted for the state led projects by this agency. If impacts occur to navigable waters (including channels and wetlands associated with Queen Creek and Newmarket Creek) permitting would require compliance with Section 10 of the Rivers and Harbors Act. These permits can typically take between three to nine months to obtain from the date of the completed application. This timeframe is dependant on the complexity of the project, the extent of the impacts, the type of actual permit required, and, often, the schedules of the regulators.

There are nine surface waters intersecting the study area corridor that have been listed as VDEQ impaired waters (Categories 4 and/or 5) on the VDEQ 2010 303(d) list. A number of additional listed stream channels are located in the vicinity of the study area. Appropriate regulations and requirements including the strict adherence to appropriate erosion and sediment control measures, the appropriate use of fertilizers, limiting clearing practices, and the implementation of stormwater management plans designed specifically to address the particular condition, as appropriate, would need to be followed as part of construction.

While the potential impacts to any groundwater well resulting from any of the Build Alternatives are likely non-existent, as noted by the VDH, potential impacts to public water distribution systems or sanitary sewage collection systems must be verified by the local utility prior to construction practices. Further investigations to determine the presence, operational status, and location of individual wells would be performed as part of property acquisition and right of way management for the construction project. Closures and/or relocation of any well, if required, would be completed by following the Virginia Waterworks Regulation and other applicable VDOT or locality standard. Closures and relocations of private wells, if required, would be completed by using the Virginia Private Well Regulation and other applicable VDOT standard or locality standard.

B. Habitat and Species Permits and Clearances

Additional federal and state agencies have statutory responsibility by serving as resource and commenting entities in the permit review process. Their involvement, for the most part, is established through the JPA process. Their general involvement in the regulatory and permitting process is summarized in the following sections.

As detailed below, a number of federal and state agencies regulate and protect listed threatened and endangered species. Due to the presence of federal and state listed threatened and endangered species and/or habitat documented within the vicinity of the study area, construction time-of-year restrictions may be required. These restrictions would be determined through the permitting process. Also, habitat assessments and species surveys may be required to determine the presence of a threatened or endangered species or habitat. These species surveys must be completed by an agency certified or approved specialist, and may have restrictions on time-of-year when the surveys can be conducted. Additional design or construction considerations, such as the use of bubble curtains, maintaining construction buffer widths, etc., may also be requested or required by the agencies.

The USFWS and the NMFS regulate and protect federally listed threatened and endangered species under the ESA of 1973 with the primary goal of conserving and recovering listed species. The ESA, with few exceptions, prohibits activities affecting threatened and endangered species unless authorized by a permit. The legal federal status of a species is determined by the USFWS and the NMFS. In addition to threatened and endangered species coordination, the NMFS would also provide comments regarding EFH for the study area corridor. Coordination with both federal agencies would continue as the project moves forward to the design phase.

In addition to the federal oversight, threatened and endangered species are also regulated at the state level by a number of different agencies and organizations. The agencies have adopted the federal list as well as

a state list of endangered and threatened species, with the primary focus of managing Virginia's wildlife to maintain optimum populations of all species and conserve biodiversity. Coordination with these agencies is conducted through the JPA process.

The VDGIF implements regulations to protect the game and freshwater fisheries of the Commonwealth, and during permit coordination, determines likely impacts on game, and fish and wildlife resources and habitats, and state-listed threatened and endangered animal species (exclusive of insects). The VDGIF also issues recommendations for mitigation measures for projects in order to avoid, minimize, and mitigate for impacts to natural resources. The VDGIF has the authority to limit construction in and around trout streams and other streams used by anadromous fish or threatened and endangered species by recommending certain time-of-year restrictions to protect spawning, fry dispersal, and or fish stocking activities, and has special powers to prevent and control aquatic invasive species.

The VDACS is charged with the conservation, protection, and management of endangered and threatened species of plants and insects (*Endangered Plant and Insect Species Act, Va. Code, Chapter 39 §3.1-1020 through 1030*, as amended). The Virginia Endangered Plant and Insect Species Program cooperates with the USFWS, the VDCR, and other agencies and organizations on the recovery, protection, or conservation of listed threatened or endangered species and designated plant and insect species that are rare throughout their worldwide ranges. In those instances where recovery plans are available, adherence to the plans is followed to the extent possible. Under a Memorandum of Agreement established between the VDACS and the VDCR, the VDCR represents the VDACS in comments regarding potential impacts on state-listed and endangered plant and insect species.

The VDCR is charged with conserving Virginia's natural and recreational resources. The Department has five programmatic divisions which manage state parks, soil and water conservation, natural heritage, recreation planning, dam safety, and floodplain management. Also included are oversight regulations by advisory bodies including the Board of Conservation and Recreation, Virginia Cave Board, Board on Conservation and Development of Public Beaches, and the Virginia Soil and Water Conservation Board. Within this agency, the Natural Heritage Program's mission is to conserve Virginia's biodiversity through inventory, protection, and stewardship, as enacted in the 1989 Virginia Natural Area Preserves Act (Va. Code §10.1-209 through 217). The VDCR's DNH is designated to conduct a statewide biological inventory, maintain a statewide database for conservation planning and project review to enhance land protection for the conservation of biodiversity, and the protection and ecological management of natural heritage resources (the habitats of rare, threatened, and endangered species, significant natural communities, geologic sites, and other natural features). This mission is carried out through implementation of four major programs: Inventory, Natural Area Protection (includes project review), and Ecological Management.

Both the VDGIF and the VDCR recommends contacting the CCB at the College of William and Mary to obtain the updated information regarding Bald eagle (*Haliaeetus leucocephalus*) issues. Although Bald eagles are currently de-listed under the federal ESA, they are still recognized as a threatened species at the state level and are protected by the federal Bald and Golden Eagle Protection Act (Eagle Act) (16 U.S.C. §668-668d) and the Migratory Bird Treaty Act (MBT Act) (16 U.S.C. §703-712).

While VIMS can provide technical advisory services to other federal and state agencies for tidal and non-tidal wetlands and marine fisheries issues, they would specifically provide comments regarding SAV issues.

C. Erosion and Sediment Control

Virginia is an authorized state under the federal National Pollutant Discharge Elimination stormwater permitting programs. The VDCR administers the Virginia Pollutant Discharge Elimination System

permitting program for the control of stormwater discharges from municipal separate storm sewer systems and land disturbing activities under the Virginia Stormwater Management Regulations (4VAC3-20). Assuming the project is pursued by the VDOT, the land-disturbing activities of greater than 2,500 square feet must comply with the most current version of the VDOT erosion and sediment control annual specifications approved by the VDCR Control Law (VESCL) and Regulations (VESCR) and the most current version of the *Virginia Erosion & Sediment Control Handbook*. All regulated land-disturbing activities must have a project specific erosion and sediment control plan developed in accordance with the VDCR approved VDOT erosion and sediment control annual specifications. All regulated land-disturbing activities associated with the project, including on and off site access roads, staging areas, borrow areas, stockpiles, and soil intentionally transported from the project must be covered by the project specific erosion and sediment control plan.

If the project is not VDOT pursued, the operator or owner of construction activities involving land disturbing activities equal to or greater than 2,500 square feet in areas designated as subject to the Chesapeake Bay Preservation Area Designation and Management Regulations adopted pursuant to the Chesapeake Bay Preservation Act are required to register for coverage under the VDCR General Permit for Discharges of Stormwater from Construction Activities and develop a project specific stormwater pollution prevention plan (SWPP). The SWPPP must be prepared prior to submission of the registration statement for coverage under the general permit and the SWPPP must address water quality and quantity in accordance with the Virginia Stormwater Management Program Permit Regulations. Any additional coordination with the counties would be required to ensure compliance with their individual regulations, including the obtainment of a County land disturbance permit, if necessary.

Although the study area corridor is located within the Chesapeake Bay Watershed, since this is a roadway project it is exempt from the commitments of the Chesapeake Bay Preservation Act regarding construction activities within the RPAs and RMAs. This exemption is contingent upon the adherence to the appropriate erosion and sediment control standards.

D. Navigation

As noted above, the USCG requires a bridge permit for the construction of a new bridge or causeway, or reconstruction or maintenance of an existing bridge or causeway across navigable waters of the United States. This authority is derived under the General Bridge Act of 1946, as amended, the Rivers and Harbors Act of 1899, as amended, and the Act of March 23, 1906, as amended, all require that the location and plans of bridges and causeways across the navigable waters of the United States be submitted to and approved by the Secretary of Transportation prior to construction. The purpose of the Bridge Permit is to preserve the public right of navigation and to prevent interference with interstate and foreign commerce. The USCG will likely review the proposed bridges associated with all of the Build Alternatives over Queen Creek in York County and Newmarket Creek in the City of Hampton. As outlined in Section M above, vessel use at these crossing is extremely low and limited to small vessels such as canoes and kayaks.

As part of the review process, and if deemed necessary, the USCG would notify all property owners a half mile up and down stream of each bridge site to issue a public notice. The agency would then assess the public's responses and then may do an Advance Approval or possibly a permit for the potential bridge site if required. At this time, it is expected that the new bridges would be of the same elevation as the existing; however, this would be determined as part of the final design of the project.

E. Coastal Zone Management Act

The Coastal Zone Management Act of 1972 enabled the Commonwealth of Virginia to develop the Virginia Coastal Zone Management Program (VCZMP) in 1986. The focus of the CZMP is to create more vital and sustainable coastal communities and ecosystems by using a network of state laws and

policies. Because the study area is located east of the fall line, all localities located within the study area are covered under Virginia's CZMP.

The Virginia CZMP is known as a "networked program", which means that to manage Virginia's coastal resources, the program relies on a network of state agencies and local governments to administer the enforceable laws and regulations that protect our wetlands, dunes, subaqueous lands, fisheries, and air and water quality – within the Virginia Coastal Zone area. The agencies involved in the CZMP include: VDEQ, VDCR, VMRC, VDGIF, VDH, VDACS, Virginia Department of Forestry, Virginia Department of Historic Resources, Virginia Department of Mines, Minerals, and Energy, VDOT, Virginia Economic Development Partnership, and VIMS.

These agencies administer the enforceable laws, regulations and advisory policies that protect coastal resources including, in part, tidal and non-tidal wetlands, fisheries, subaqueous lands, dunes and beaches, point source air pollution, point source and non-point source water pollution, shoreline sanitation, coastal lands, spawning/nursery/feeding grounds, coastal primary sand dunes, barrier islands, significant wildlife habitat areas, significant public recreation areas, significant sand and gravel resource deposits, underwater historic resources, highly erodible/high hazard areas, and waterfront development area. Several of this project's relevant coastal zone management resources are addressed in detail in other sections of this document.

Projects that are located within the Coastal Zone Management Area (CZMA) in Virginia which are, at least in part, federally-funded or require federal approval must undergo a federal consistency certification process. The goal of this process is to ensure that projects are designed to avoid and/or minimize impacts to specific coastal resources as identified by several enforceable policies related to fisheries, subaqueous lands, tidal and non-tidal wetlands, dunes, non-point and point source pollution control, shoreline sanitation, air pollution, and land management. In Virginia, the VDEQ is responsible for coordinating the Commonwealth's review of federal consistency determination and certification with the cooperating agencies and responding to the appropriate federal agency or applicant. All member agencies of the VCZMP would be notified of the proposed project through the JPA permitting process and the document review. While the JPA process required for the Sections 401 and 404 of the CWA and VMRC permits (described above) would address all resources and requirements associated with the CZMA Program, the completion of the CZMA checklist may also be required.
